YOUR HEATHKIT 90-DAY LIMITED WARRANTY

For a period of ninety (90) days after purchase, Heath Company will replace or repair free of charge any parts that are defective either in materials or workmanship. You can obtain parts directly from Heath Company by writing us at the address below or by telephoning us at (616) 982-3571. And we'll pay shipping charges to get those parts to you — anywhere in the world.

We warrant that during the first ninety (90) days after purchase, our products, when correctly assembled, calibrated, adjusted and used in accordance with our printed instructions, will meet published specifications.

If a defective part or error in design has caused your Heathkit product to malfunction during the warranty period through no fault of yours, we will service it free upon proof of purchase and delivery at your expense to the Heath factory, any Heathkit Electronic Center, or any of our authorized overseas distributors.

You will receive free consultation on any problem you might encounter in the assembly or use of your Heathkit product. Just drop us a line or give us a call. Sorry, we cannot accept collect calls.

Our warranty does not cover and we are not responsible for damage caused by: incorrect assembly, the use of corrosive solder, defective tools, misuse, or fire; or by unauthorized modifications to or uses of our products for purposes other than as advertised. Our warranty does not include reimbursement for inconvenience, loss of use, customer assembly or set-up time.

This warranty covers only Heathkit products and is not extended to allied equipment or components used in conjunction with our products. **We are not responsible for accidental or consequential damages.** Some states do not allow the exclusion or limitation of incidental or consequential damages, so the above limitation or exclusion may not apply to you. This warranty gives you specific legal rights, and you may also have other rights which vary from state to state.

If you are not satisfied with our service (warranty or otherwise) or with our products, write directly to our Director of Customer Services, Heath Company, Benton Harbor, Michigan 49022. He will make certain your problems receive immediate, personal attention.

HEATH COMPANY

INTRODUCTION

The ET-3400 Microcomputer Learning System is a practical, low cost microprocessor trainer; designed as a learning tool to teach microprocessor operation, programming, and applications. The ET-3400 Trainer is designed to accompany the EE-3401 Individual Learning Program on microprocessors. All of the programming and hardware interface experiments supplied with this course are implemented on the Trainer. While the Trainer was designed primarily to accompany this course, it is a flexible, general-purpose training unit and microprocessor breadboard. It can be used in many other applications that require a low cost microprocessor-based software development system or as a design aid for developing special interfaces.

MAIN FEATURES

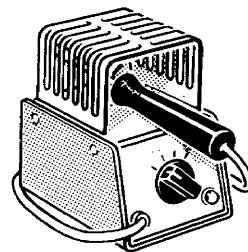

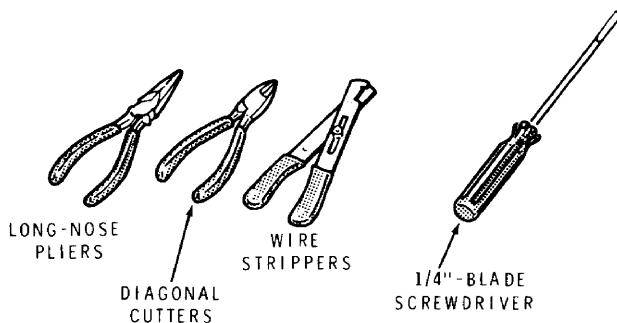

- Uses the popular 6800 Microprocessor.
- Is supplied with 256 bytes of semiconductor RAM (expandable to 512 bytes).
- Features 1K ROM monitor program.
- Has hexadecimal keyboard for rapid data and program entry.
- Has six digits of hexadecimal display for reading out memory addresses, their contents, and register contents.

- Uses breadboarding sockets that permit rapid, solderless assembly of IC logic circuitry to be used with the microprocessor. They are ideal for prototyping special interface circuits.
- The microprocessor address bus, data bus, control lines, and associated signals are buffered and terminated on front panel connectors; allowing complete freedom in experimenting with the microprocessor and its associated circuitry.
- Has eight individual, independent, binary LED indicators for monitoring logic states in the breadboard circuitry.
- Has eight individual, independent, binary data switches that can be used for supplying binary words and logic levels in the breadboarding circuitry.
- The built-in power supplies furnish power to all internal circuitry and have sufficient reserve to power breadboard circuits. The +5 and ± 12 -volt supply voltages are connected to front panel connectors.
- Has provision for future expansion of memory and I/O capabilities.

NUT
DRIVERS

*TO REMOVE SOLDER FROM CIRCUIT CONNECTIONS.

ASSEMBLY

1. Follow the instructions carefully. Read the entire step before you perform each operation.
2. The illustrations in the Manual are called Pictorials and Details. Pictorials show the overall operation for a group of assembly steps; Details generally illustrate a single step. When you are directed to refer to a certain Pictorial "for the following steps," continue using that Pictorial until you are referred to another Pictorial for another group of steps.
3. Most kits use a separate "Illustration Booklet" that contains illustrations (Pictorials, Details, etc.) that are too large for the Assembly Manual. Keep the "Illustration Booklet" with the Assembly Manual. The illustrations in it are arranged in Pictorial number sequence.
4. Position all parts as shown in the Pictorials.
5. Solder a part or a group of parts only when you are instructed to do so.

6. Each circuit part in an electronic kit has its own component number (R2, C4, etc.). Use these numbers when you want to identify the same part in the various sections of the Manual. These numbers, which are especially useful if a part has to be replaced, appear:
 - In the Parts List,
 - At the beginning of each step where a component is installed,
 - In some illustrations,
 - In the Schematic,
 - In the section at the rear of the Manual.
7. When you are instructed to cut something to a particular length, use the scales (rulers) provided at the bottom of the Manual pages.

SAFETY WARNING: Avoid eye injury when you cut off excess lead lengths. Hold the leads so they cannot fly toward your eyes.

SOLDERING

Soldering is one of the most important operations you will perform while assembling your kit. A good solder connection will form an electrical connection between two parts, such as a component lead and a circuit board foil. A bad solder connection could prevent an otherwise well-assembled kit from operating properly.

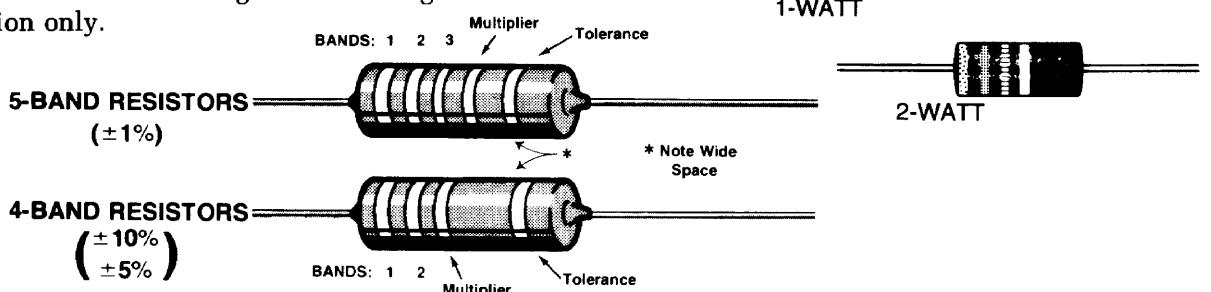

It is easy to make a good solder connection if you follow a few simple rules:

1. Use the right type of soldering iron. A 25 to 40-watt pencil soldering iron with a 1/8" or 3/16" chisel or pyramid tip works best.
2. Keep the soldering iron tip clean. Wipe it often on a wet sponge or cloth; then apply solder to the tip to give the entire tip a wet look. This process is called tinning, and it will protect the tip and enable you to make good connections. When solder tends to "ball" or does not stick to the tip, the tip needs to be cleaned and retinned.

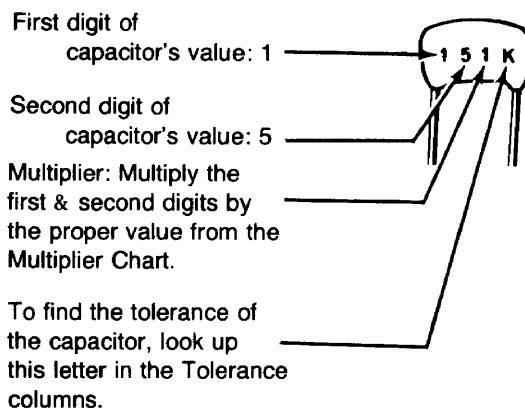

PARTS

Resistors will be called out by their resistance value in Ω (ohms), $k\Omega$ (kilohms), or $M\Omega$ (megohms). Certain types of resistors will have the value printed on the body, while others will be identified by a color code. The colors of the bands and the value will be given in the steps, therefore the following color code is given for information only.

Band 1 1st Digit		Band 2 2nd Digit		Band 3 (if used) 3rd Digit		Multiplier		Resistance Tolerance	
Color	Digit	Color	Digit	Color	Digit	Color	Multiplier	Color	Tolerance
Black	0	Black	0	Black	0	Black	1	Silver	$\pm 10\%$
Brown	1	Brown	1	Brown	1	Brown	10	Gold	$\pm 5\%$
Red	2	Red	2	Red	2	Red	100	Brown	$\pm 1\%$
Orange	3	Orange	3	Orange	3	Orange	1,000		
Yellow	4	Yellow	4	Yellow	4	Yellow	10,000		
Green	5	Green	5	Green	5	Green	100,000		
Blue	6	Blue	6	Blue	6	Blue	1,000,000		
Violet	7	Violet	7	Violet	7	Violet	0.01		
Gray	8	Gray	8	Gray	8	Gray	0.1		
White	9	White	9	White	9	White			

Capacitors will be called out by their capacitance value in μF (microfarads) or pF (picofarads) and type: ceramic, Mylar*, electrolytic, etc. Some capacitors may have their value printed in the following manner:

EXAMPLES:

$$151K = 15 \times 10 = 150 \text{ pF}$$

$$759 = 75 \times 0.1 = 7.5 \text{ pF}$$

NOTE: The letter "R" may be used at times to signify a decimal point: as in: 2R2 = 2.2 (pF or μF).

FOR THE NUMBER:	MULTIPLY BY:	TOLERANCE OF CAPACITOR		
		10 pF OR LESS	LETTER	OVER 10 pF
0	1	$\pm 0.1 \text{ pF}$	B	
1	10	$\pm 0.25 \text{ pF}$	C	
2	100	$\pm 0.5 \text{ pF}$	D	
3	1000	$\pm 1.0 \text{ pF}$	F	$\pm 1\%$
4	10,000	$\pm 2.0 \text{ pF}$	G	$\pm 2\%$
5	100,000		H	$\pm 3\%$
			J	$\pm 5\%$
8	0.01		K	$\pm 10\%$
9	0.1		M	$\pm 20\%$

PARTS LIST

Check each part against the following list. Any part that is packed in an individual envelope with the part number on it should be placed back in the envelope after you identify it until it is called for in a step. Do not discard any packing materials until all parts are accounted for.

The key numbers correspond to the numbers on the "Parts Pictorial" in the separate "Illustration Booklet" on Pages 1 and 2.

To order a replacement part: Always include the PART NUMBER. Use the Parts Order Form furnished with the kit. If one is not available, see "Replacement Parts" inside the rear cover of the Manual. Your Warranty is located inside the front cover. For prices, refer to the separate "Heath Parts Price List."

RESISTORS

NOTES:

1. All resistors are 10% tolerance unless otherwise noted. A fourth color band of silver indicates a 10% tolerance; a fourth band of gold indicates 5% tolerance.
2. The resistors may be packed in more than one envelope. Open all the resistor envelopes in this pack before you check them against the Parts List.

STEP-BY-STEP ASSEMBLY

The steps performed in this Pictorial are in this area of the circuit board.

MAIN CIRCUIT BOARD

START ▶

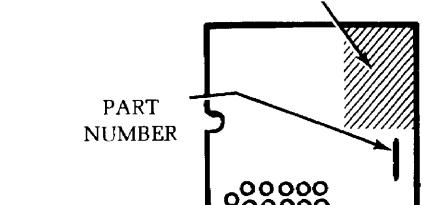

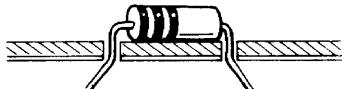

In the following steps you will be given detailed instructions on how to install and solder the first part on the circuit board. Read and perform each step carefully. Then use the same procedure whenever you install parts on a circuit board.

() Position the circuit board as shown in the identification drawing with the printed side up.

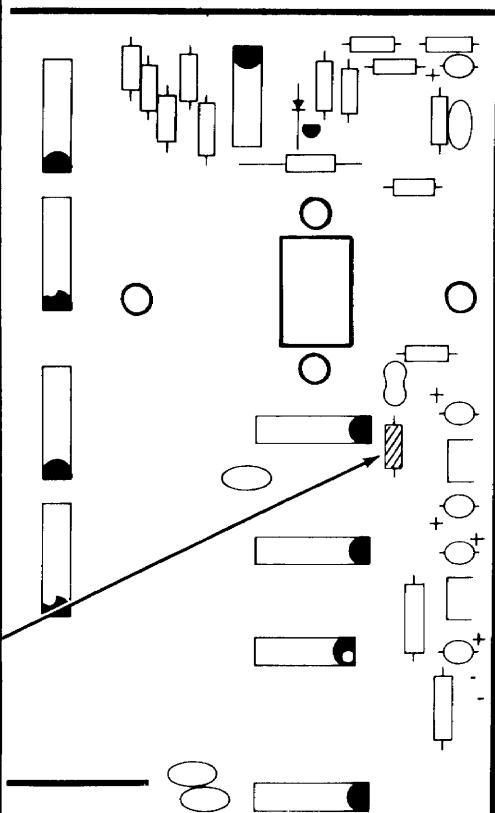

() R49: Hold a 1200 Ω (brown-red-red) resistor by the body as shown and bend the leads straight down.

() Push the leads through the holes at the indicated location on the circuit board. The end with color bands may be positioned either way.

() Press the resistor against the circuit board. Then bend the leads outward slightly to hold the resistor in place.

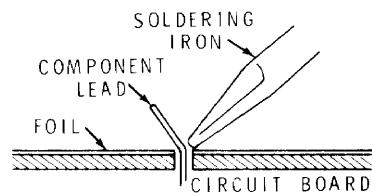

IDENTIFICATION
DRAWING

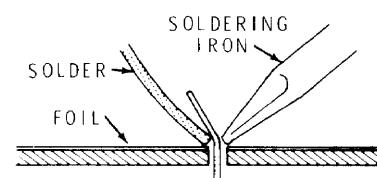

CONTINUE ▶

() Solder the resistor leads to the circuit board as follows:

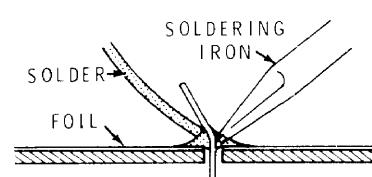

- Push the soldering iron tip against both the lead and the circuit board foil. Heat **both** for two or three seconds.

- Then apply solder to the other side of the connection. **IMPORTANT:** Let the heated lead and the circuit board foil melt the solder.

- As the solder begins to melt, allow it to flow around the connection. Then remove the solder and the iron and let the connection cool.

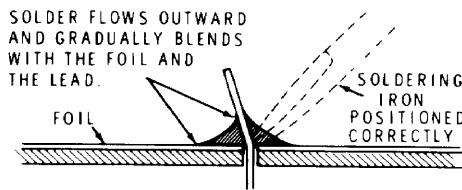

- Hold the lead with one hand while you cut off the excess lead length close to the connection. This will keep you from being hit in the eye by the flying lead.

- Check the connection. Compare it to the illustrations on the next page. After you have checked the solder connections, proceed with the assembly on page 12. Use the same soldering procedure for each connection.

PICTORIAL 1-1

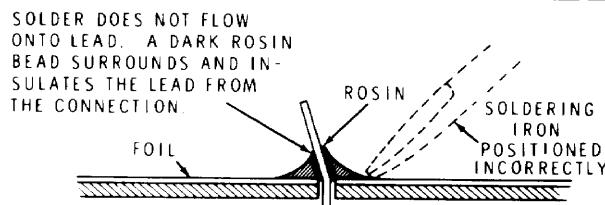

A GOOD SOLDER CONNECTION

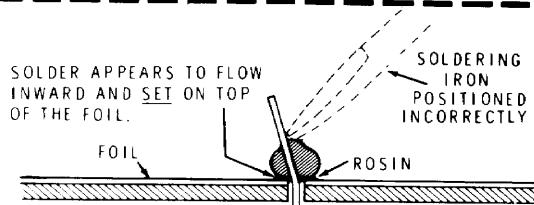

When you heat the lead and the circuit board foil at the same time, the solder will flow evenly onto the lead and the foil. The solder will make a good electrical connection between the lead and the foil.

POOR SOLDER CONNECTIONS

When the lead is not heated sufficiently, the solder will not flow onto the lead as shown above. To correct, reheat the connection and, if necessary, apply a small amount of additional solder to obtain a good connection.

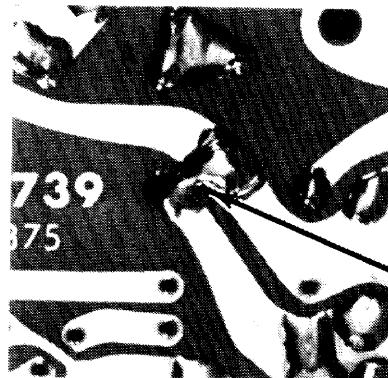

When the foil is not heated sufficiently the solder will blob on the circuit board as shown above. To correct, reheat the connection and, if necessary, apply a small amount of additional solder to obtain a good connection.

SOLDER BRIDGES

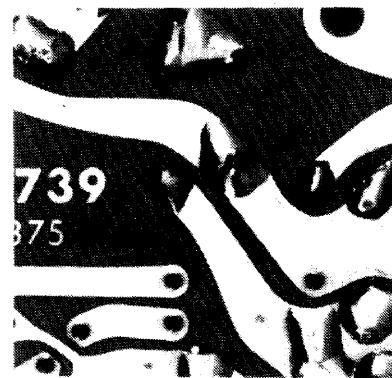

A solder bridge between two adjacent foils is shown in photograph A. Photograph B shows how the connection should appear. A solder bridge may occur if you accidentally touch an adjacent previously soldered connection, if you use too much solder, or if you "drag" the soldering iron across other foils as you remove it from the connection. A good rule to follow is: always take a good look at the foil area around each lead before you solder it. Then, when you solder the connection, make sure the solder remains in this area and does not bridge to another foil. This is especially important when the foils are small and close together. NOTE: It is alright for solder to bridge two connections on the same foil.

Use only enough solder to make a good connection, and lift the soldering iron straight up from the circuit board. If a solder bridge should develop, turn the circuit board foil-side-down and heat the solder between connections. The excess solder will run onto the tip of the soldering iron, and this will remove the solder bridge. NOTE: The foil side of most circuit boards has a coating on it called "solder resist." This is a protective insulation to help prevent solder bridges.

PART NUMBER

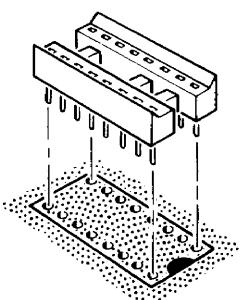

IDENTIFICATION
DRAWING

MAIN CIRCUIT BOARD

START ↓

NOTE: When you install an IC socket, use the following procedure:

1. Be sure all the pins are straight.
2. Insert the pins into the holes.
3. Turn the circuit board over and be sure the correct number of pins extend from the board. If not, one or more pins may be bent under the socket. Remove the socket, straighten the pins, and reinstall the socket.
4. Solder the pins to the foil as you install each socket.
NOTE: Some socket pins will have no foil pads; do not solder these pins.

16-pin IC sockets at the seven following locations:

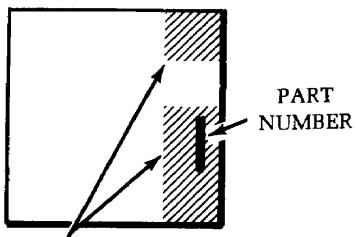

- IC14. IC19.
- IC15. IC20.
- IC16. IC22.
- IC17.

NOTE: Be sure you install the first resistor (Page 10).

PICTORIAL 1-2

IDENTIFICATION
DRAWING

The steps performed in this Pictorial are in these areas of the circuit board.

NOTE: Hold the leads with a pair of long-nosed pliers close to the body of the diode. Then bend the leads down.

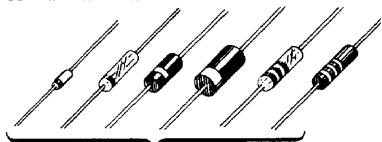

Detail 1-3A

START ▶

- () Install thirty 470 Ω (yellow-violet-brown) resistors in the area shown. After you install each group of five or six resistors, solder their leads to the foil and cut off the excess lead lengths. NOTE: See "Circuit Board X-RAY Views" in the "Illustration Booklet" for circuit component numbers.

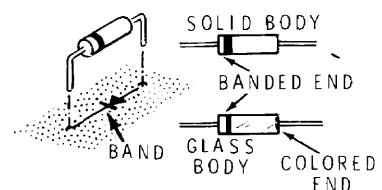

In the next column you will install diodes. Be sure you install each diode as follows.

IMPORTANT: THE BANDED END OF DIODES CAN BE MARKED IN A NUMBER OF WAYS.

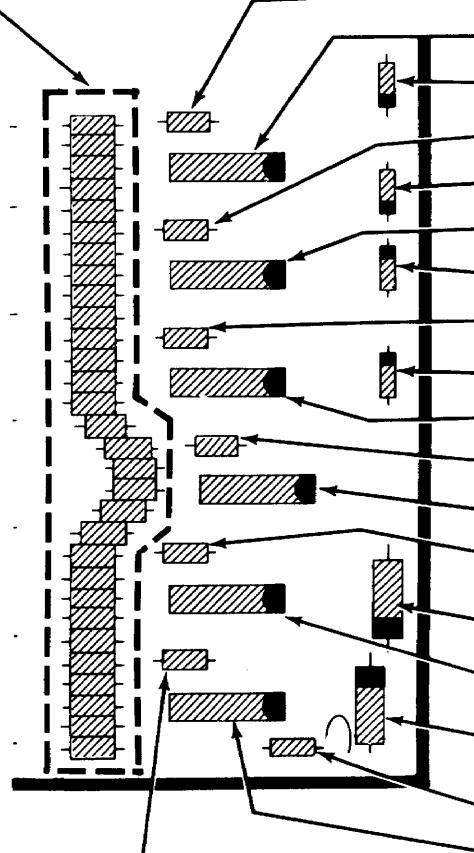

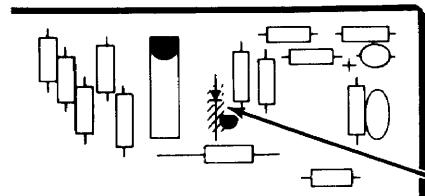

BANDED END

CAUTION: ALWAYS POSITION THE BANDED END AS SHOWN ON THE CIRCUIT BOARD.

If your diode has a solid body, the band is clearly defined. If your diode has a glass body, do not mistake the colored end inside the diode for the banded end. Look for a band painted on the outside of the glass.

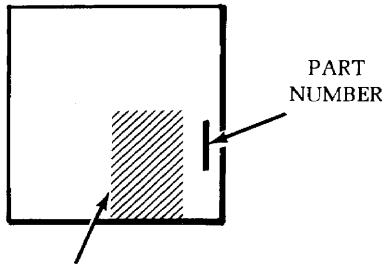

CONTINUE ▶

NOTE: As you install the remaining components on this Pictorial, solder the leads to the foil and cut off the excess lead lengths.

PICTORIAL 1-9

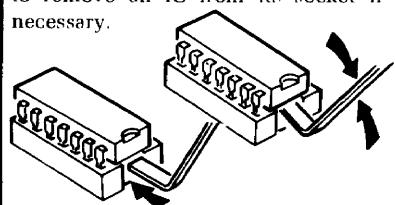

START ▶

In the following steps, install IC's in the designated sockets. Be careful to match the pin 1 end of each IC to the index mark on the circuit board. See Detail 1-10A.

Before you apply downward pressure to an IC, make sure each IC pin is centered in its proper socket hole. Handle IC's with care, as their pins bend very easily.

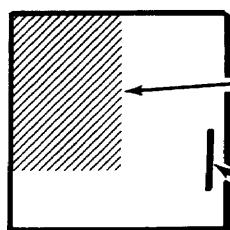

NOTE: An IC puller has been furnished to remove an IC from its socket if necessary.

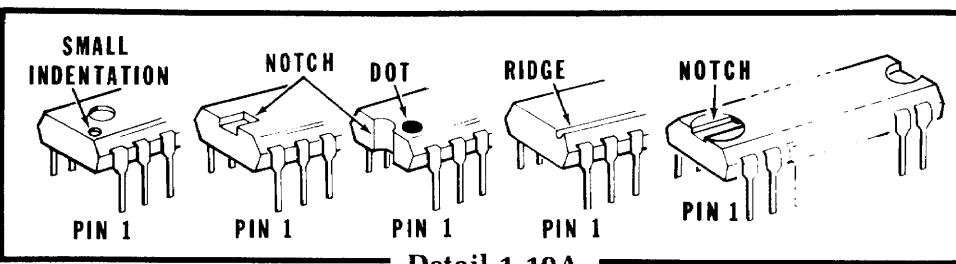

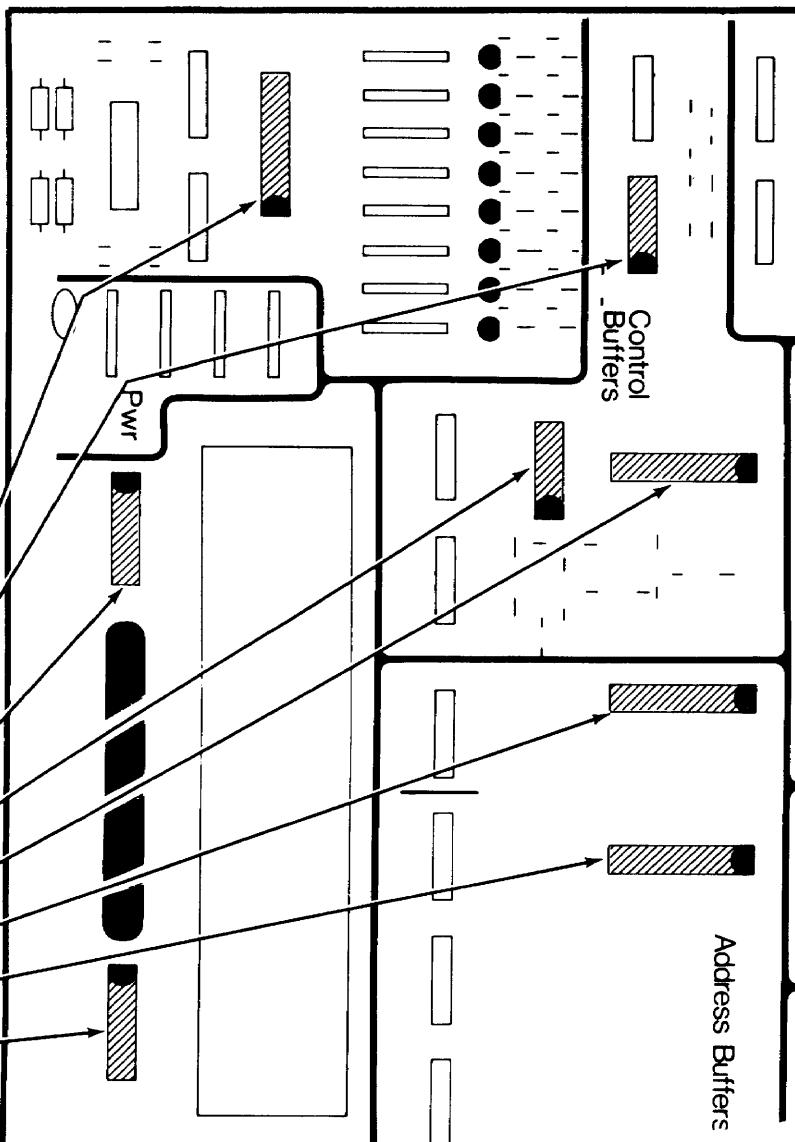

Push the shorter end of the puller in between the IC and the socket and rock the longer portion back and forth. Be very careful, as the IC pins are very easily bent.

- () IC1: 74LS241 (#443-824).
- () IC4: 74126N (#443-717).
- () IC2: 74LS42 (#443-807). Be sure to notice the index mark on the circuit board.
- () IC5: 74S00 (#443-26).
- () IC6: 74LS241 (#443-824).
- () IC7: 74LS241 (#443-824).
- () IC8: 74LS241 (#443-824).

The steps performed in this Pictorial are in this area of the circuit board.

IDENTIFICATION
DRAWING

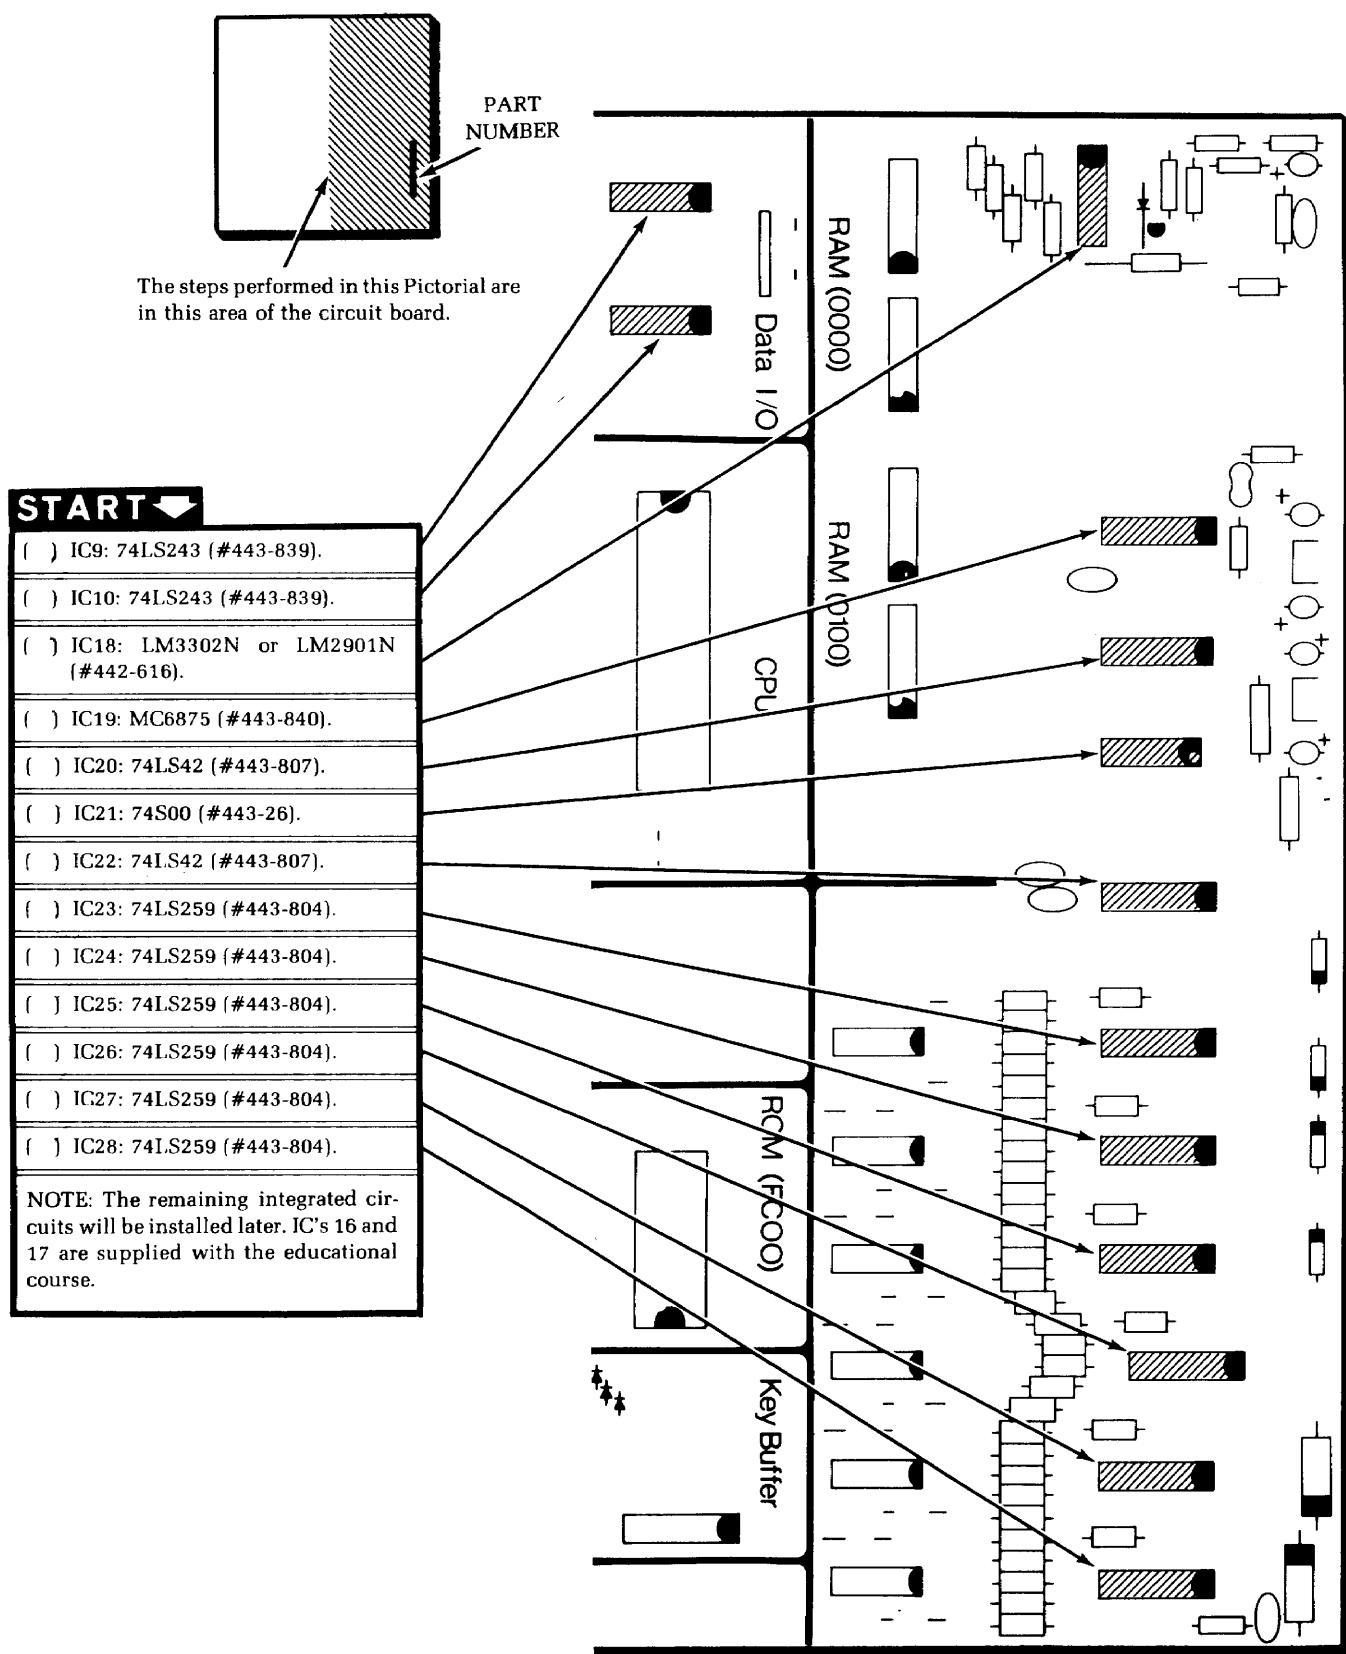

Detail 1-10A.

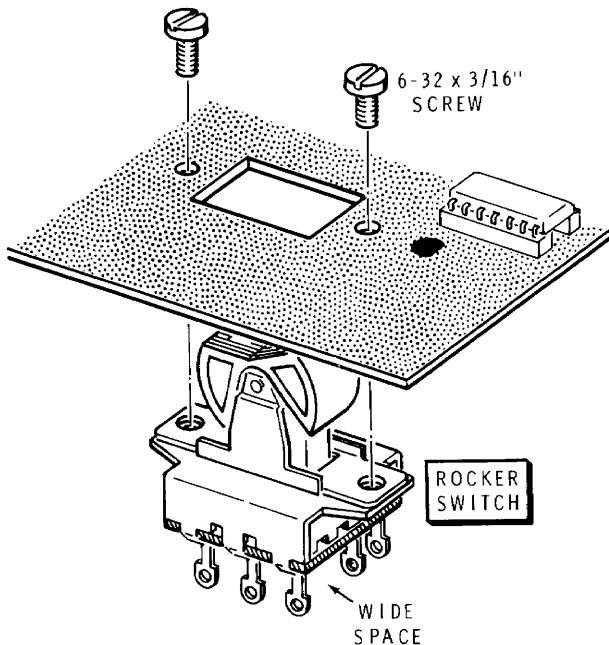

PICTORIAL 1-10

IDENTIFICATION
DRAWING

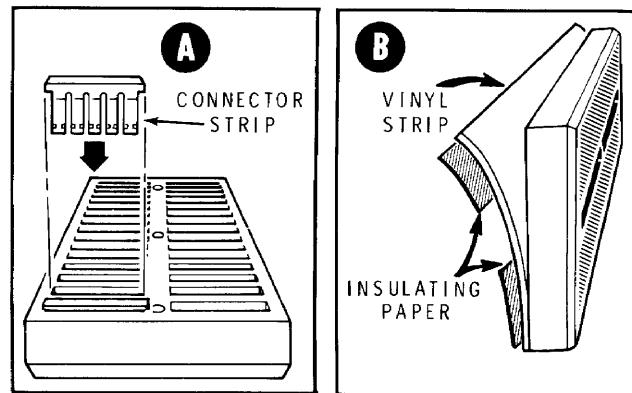

PICTORIAL 1-11

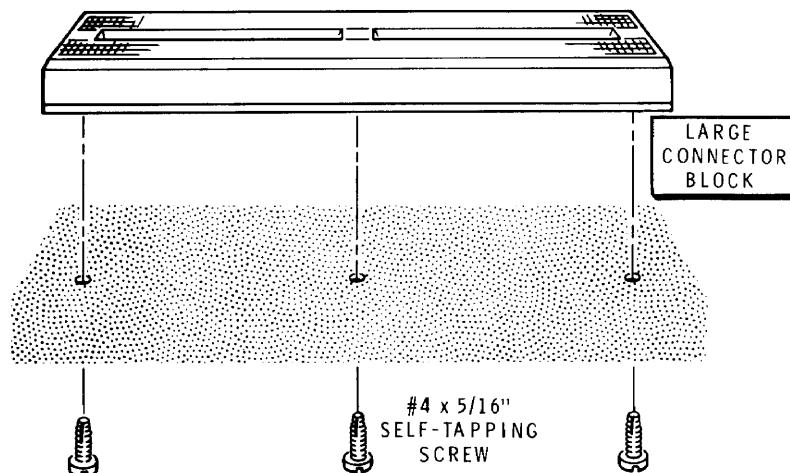

**Detail 1-12A**

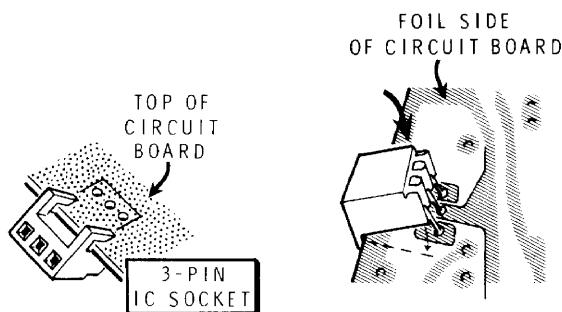

Refer to Pictorial 1-12 (Illustration Booklet, Page 3) for the following steps.

- () Reposition the main circuit board as shown.
- () SW1: Refer to Detail 1-12A and mount the rocker switch on the main circuit board at SW1 with two $6-32 \times 3/16"$ screws. Install the switch so the lugs are positioned as shown in the Detail.

**Detail 1-12B**

- () Refer to Part A of Detail 1-12B and install the connector strips (supplied with the large connector block) into the block in the manner shown. NOTE: You may have some connector strips left over.
- () Turn the connector block right side up, and with a screwdriver handle or similar tool, tap on the top of the block until all the connector strips are fully seated up into the block.
- () Refer to Part B of Detail 1-12B and remove the paper backing from the vinyl strip supplied with the connector block. Position the connector as shown, line up the long edge of the vinyl strip with the long edge of the connector block, and firmly press the strip onto the block.
- () Refer to Detail 1-12B and remove the backing paper from the insulating paper. Then apply the insulating paper along the indicated edges of the vinyl strip. Keep the paper even with the edges of the large connector block.

**Detail 1-12C**

Detail 1-12D

- () With the tip of a pencil, push through the three mounting hole locations in the vinyl strip.
- () Refer to Detail 1-12C and mount the large connector block on the main circuit board with three #4 × 5/16" self-tapping screws.
- () Refer to Detail 1-12D and mount a 3-pin IC socket at IC29 on the top edge of the circuit board as shown. Place the edge-mount retainers over the edge of the circuit board; then rotate the pins into their holes on the **foil side** of the board. Carefully solder the three pins to the foil.
- () In the same manner, install a 3-pin IC socket at IC30.
- () LED1: Refer to Detail 1-12E and mount the 3/8" red LED near the rocker switch as shown. Be sure to match the flat on the LED with the outline of the flat on the circuit board. NOTE: Before you cut off the excess leads, be sure the bottom edge of the LED is 1/4" above the board, and that it is not tilted. Solder the leads to the foil.

CIRCUIT BOARD CHECKOUT

Carefully inspect the foil side of the circuit board for the following conditions.

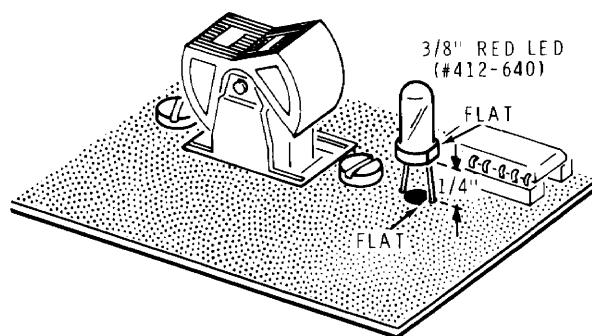

- () Unsoldered connections.
- () Poor solder connections.
- () Solder bridges between foil patterns. NOTE: If you are in doubt about a foil pattern, refer to the "Circuit Board X-Ray View" (Illustration Booklet, Page 18).
- () Protruding leads which could touch together.

Carefully inspect the component side of the circuit board for the following conditions.

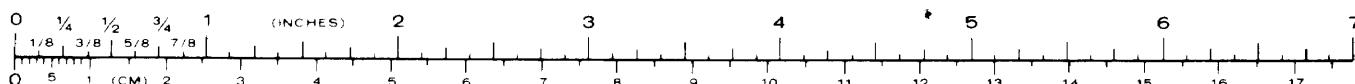

- () Integrated circuits for proper type and installation.
- () Tantalum capacitors for the correct position of the positive (+) mark or dot.
- () Diodes for the correct position of the banded ends.
- () LED's for the correct position of the flat sides.

NOTE: There are many unused connections on the foil side of the main circuit board, some of which will be used later. As you make further connections to the circuit board, be sure to inspect each one carefully to be sure the foils remain unbridged.

Set the main circuit board aside temporarily.

Detail 1-12E

KEYBOARD CIRCUIT BOARD

START ▶

Position the keyboard circuit board as shown. Then proceed with the following steps.

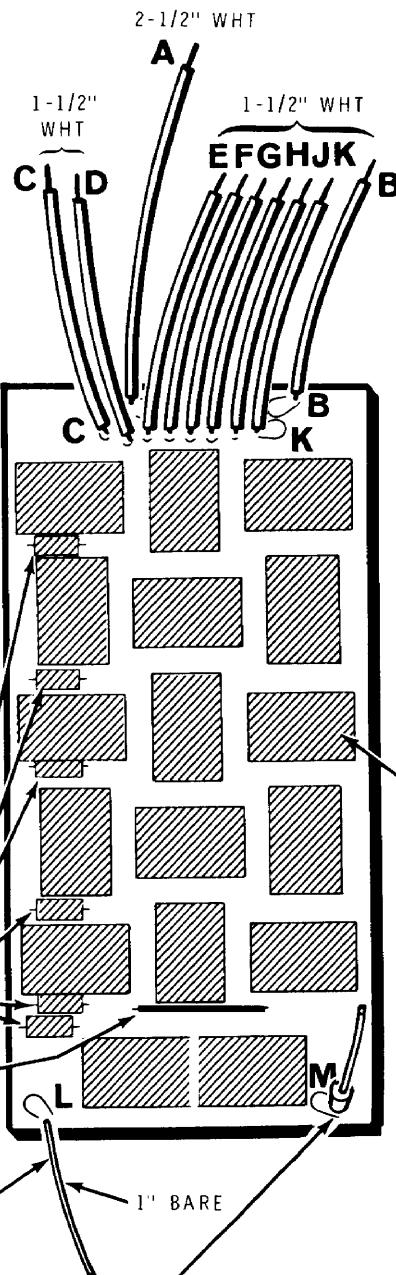

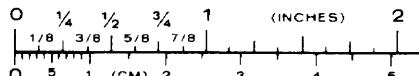

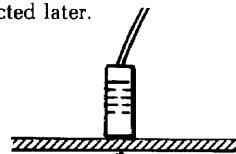

NOTE: To prepare a wire, as in the following step, cut it to the indicated length and remove 1/4" of insulation from each end. If the wire is stranded, tightly twist each wire end and apply a small amount of solder to hold the fine strands together.

- () Prepare the following wires:

One 2-1/2" white stranded
Nine 1-1/2" white stranded
One 1-3/8" yellow

As you install a prepared wire in the following steps, solder it to the foil and cut off the excess wire length.

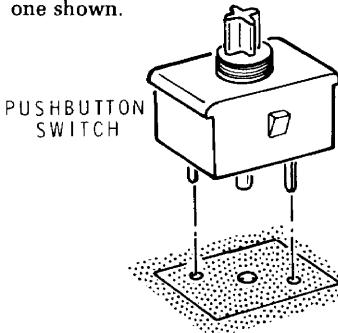

- () 2-1/2" white wire at A.
- () Nine 1-1/2" white wires at B through K.
- () R52 through R57: Install six 8200 Ω (gray-red-red) resistors. Solder the leads to the foil and cut off the excess lead lengths.
- () 1-3/8" yellow wire jumper.
- () Remove the insulation from 1" of brown wire. Then cut off this bare wire.
- () 1" bare wire at L.
- () R107: 180 Ω (brown-gray-brown). Mount it vertically down on the circuit board, solder the lead to the foil, and cut off the excess lead length. The free lead will be connected later.

PICTORIAL 2-1

CONTINUE ▶

As you install pushbutton switches in the following step, be sure each key is down against the top of the keyboard before you solder its two lugs. Your switches may look different than the one shown.

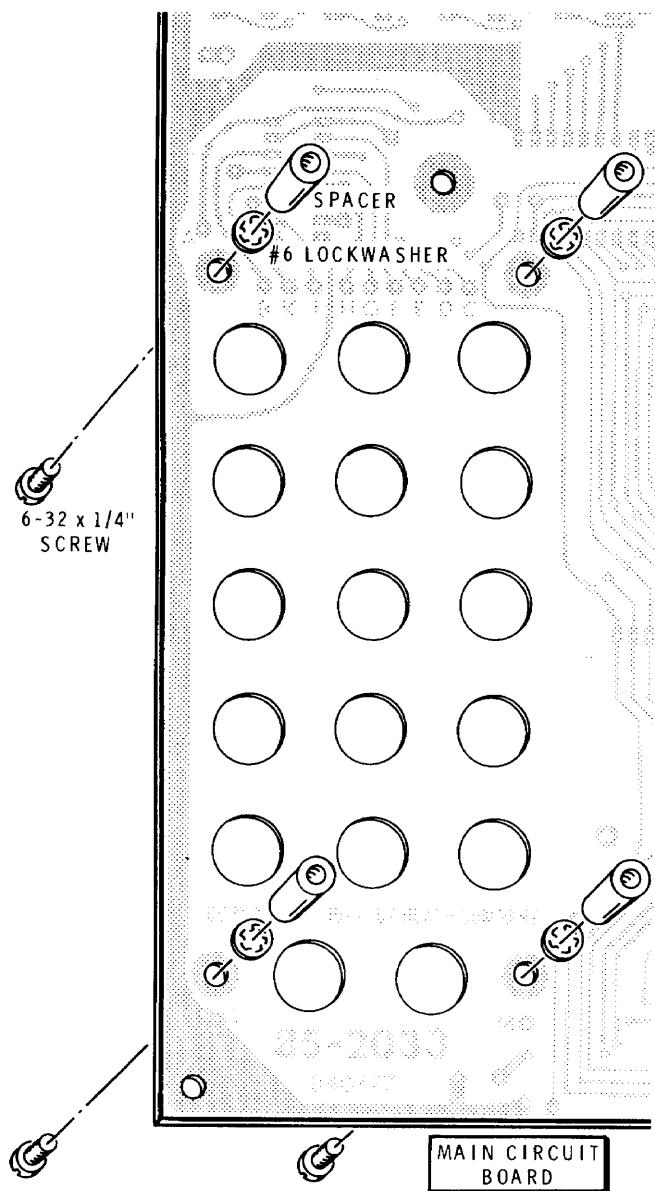

- () 17 pushbutton switches.

CIRCUIT BOARD CHECKOUT

Carefully inspect the circuit board for the following conditions.

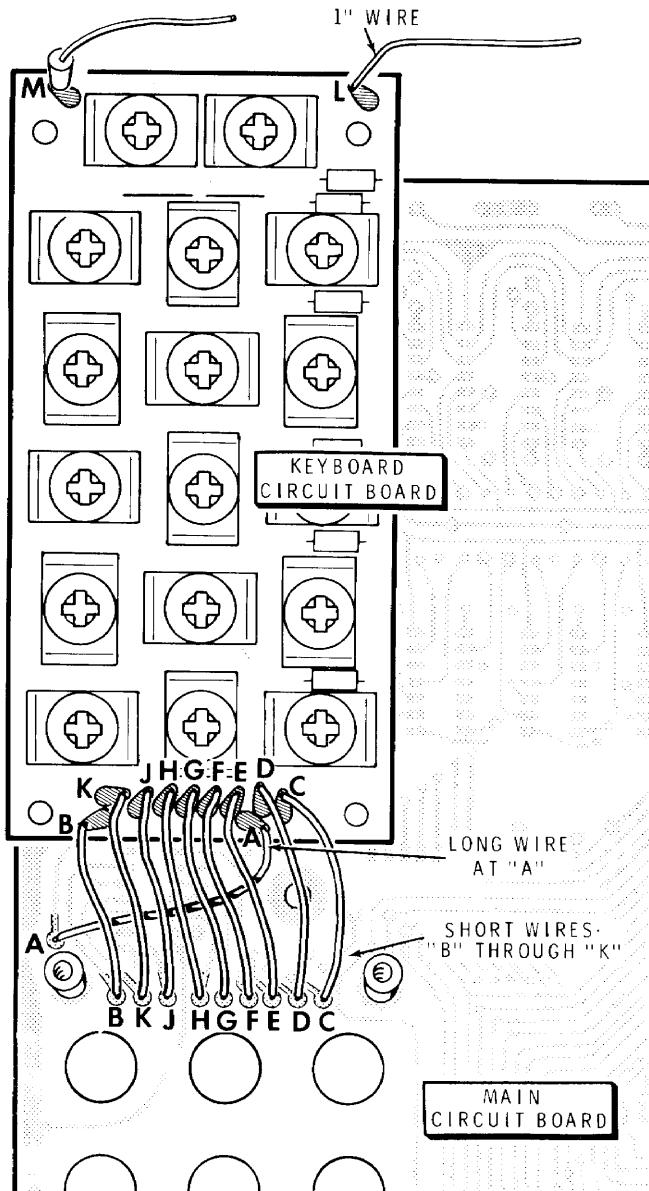

- () Unsoldered connections.
- () "Cold" solder connections.
- () Solder bridges between foil patterns.
- () Protruding leads which could touch together.

Detail 3-1A

Refer to Pictorial 3-1 (Illustration Booklet, Page 3) for the following steps.

- () Refer to Detail 3-1A, turn the main circuit board upside down, and loosely mount spacers onto the foil side at the four locations shown in the Pictorial. Use 6-32 × 1/4" screws and #6 lockwashers.

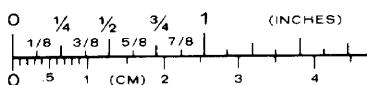

Detail 3-1B

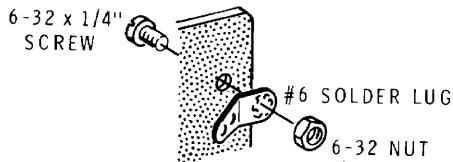

- () Position the keyboard circuit board, foil-side down, onto the main circuit board as shown in Detail 3-1B.

NOTE: As you install each wire, push it into its designated hole and leave approximately $1/16$ " of the bare wire above the foil so it will make a good solder connection. Solder each wire to the foil as it is installed and cut off the excess wire ends on the top of the circuit board.

Connect the wires coming from the keyboard circuit board to the main circuit board:

- () Wire B to B.
- () Wire K to K.
- () Wire J to J.
- () Wire H to H.
- () Wire G to G.
- () Wire F to F.
- () Wire E to E.
- () Wire A to A.
- () Wire D to D.
- () Wire C to C.
- () Flip the keyboard circuit board over, end-for-end, (keep the wires out of the way) and position the tops of the pushbutton switches into their corresponding holes in the main circuit board. (If your switches have springs and brass washers, you may have to force them through the holes).
- () Connect the wire coming from keyboard hole L to hole M on the main circuit board. **Do not** solder the connection.
- () Connect the resistor coming from keyboard hole M to hole L on the main circuit board. **Do not** solder the connection.
- () Loosely install four $6-32 \times 1/4$ " screws and #6 lockwashers at the keyboard corner holes. Turn the screws into the spacers as shown.
- () On the top of the main circuit board, tighten the four $6-32$ screws to secure the spacers; then tighten the four keyboard mounting screws.
- () Solder the wire and resistor lead to the main circuit board at L and M and cut off the excess lengths.

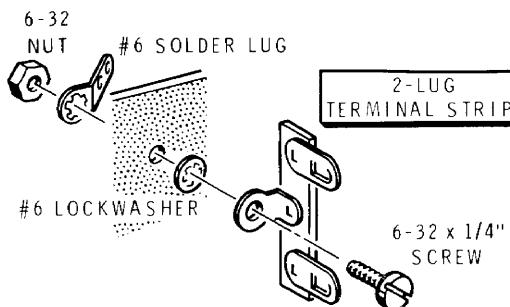

Detail 4-1A

SUPPORT BRACKET ASSEMBLY

Refer to Pictorial 4-1 (Illustration Booklet, Page 4) for the following steps.

- () Position the support bracket on your work area as shown.
- () Refer to Detail 4-1A and mount a solder lug at A with a $6-32 \times 1/4"$ screw and a $6-32$ nut. Position the solder lug as shown in the Pictorial.
- () Press a rubber grommet into hole B.
- () Refer to Detail 4-1B and mount a 2-lug terminal strip at C. Use a $6-32 \times 1/4"$ screw, #6 lockwasher, #6 solder lug, and $6-32$ nut. Position the terminal strip and solder lug as shown in the Pictorial.
- () Cut the lead at the **positive (+)** end of a $1200 \mu\text{F}$ electrolytic capacitor (#25-241) to $1/2"$.

NOTE: In the following steps, (NS) means not to solder a connection because other wires or leads will be connected later. "S—" with a number, such as (S-2),

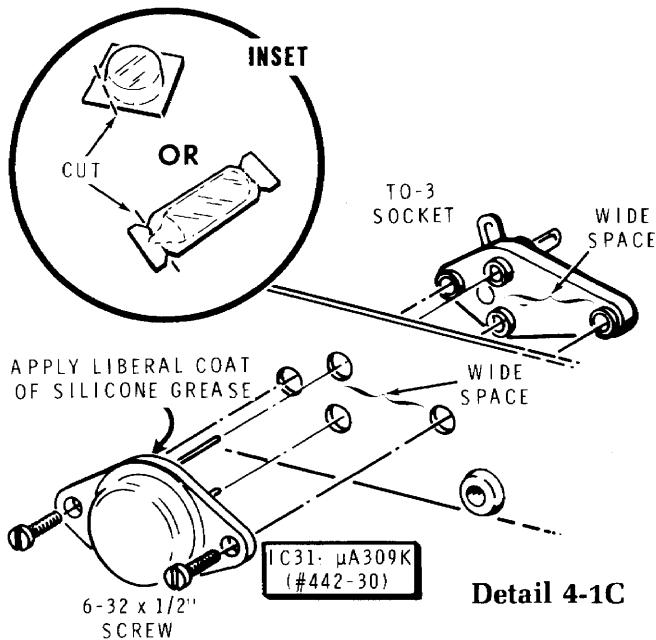

Detail 4-1B

means to solder the connection. The number following the "S" tells how many wires are at the connection.

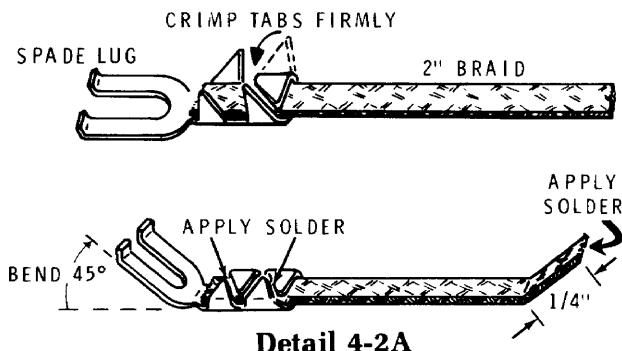

- () C6: Connect the **positive (+)** lead of a $1200 \mu\text{F}$ capacitor to terminal strip C lug 1 (NS) and the negative lead to solder lug A (NS). Position the capacitor as shown in the Pictorial.
- () Cut the lead at the negative (unmarked) end of another $1200 \mu\text{F}$ electrolytic capacitor to $1/2"$.
- () C7: Connect the **negative (-)** lead of the other $1200 \mu\text{F}$ capacitor to terminal strip C lug 2 (NS) and the positive (+) lead to solder lug A (S-2).

Refer to Detail 4-1C for the next two steps.

- () Refer to the inset drawing on Detail 4-1C and open the container of silicone grease. Apply a liberal coating of the grease to the bottom of the $\mu\text{A}309\text{K}$ integrated circuit (#442-30).
- () IC31: Carefully observe the wide spacing on the IC holes in the support bracket at IC31 and place the TO-3 socket on the underside of the bracket as shown in the Detail. Be sure the shoulders of the socket are centered in the two end holes. Then push the pins of the $\mu\text{A}309\text{K}$ IC into the socket, through the support bracket. Making sure the socket shoulders are still centered in their holes, secure the IC with two $6-32 \times 1/2"$ screws.

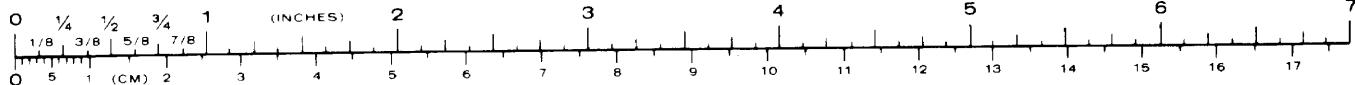

Detail 4-1C

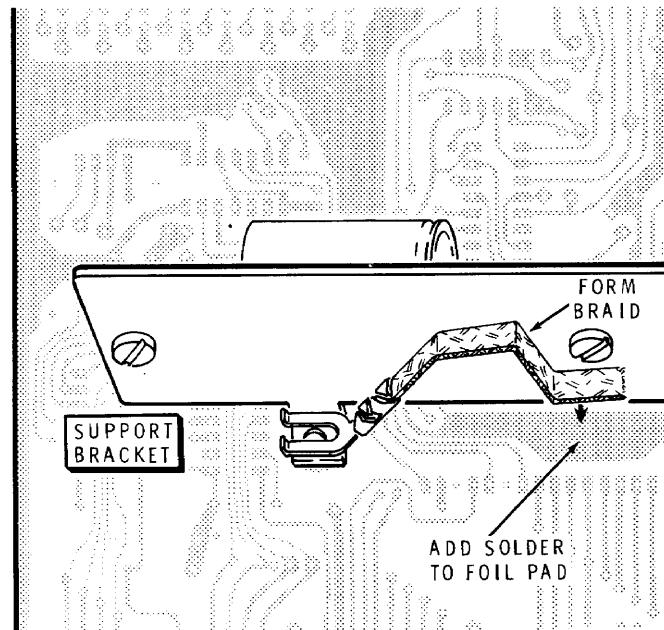

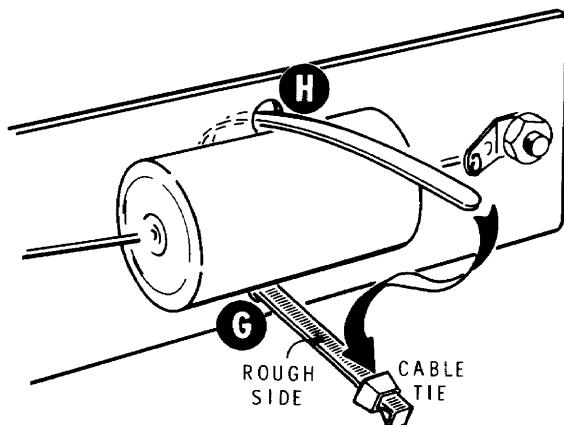

Refer to Pictorial 4-2 (Illustration Booklet, Page 4) for the following steps.

- () Reposition the support bracket as shown.
- () As you did in Detail 4-1A, mount a #6 solder lug at D with a 6-32 × 1/4" screw and a 6-32 nut. Position the solder lug as shown in the Pictorial.
- () Cut a 1-3/4" piece of sleeving.
- () C1: Cut the negative (unmarked) lead of the 6000 μ F electrolytic capacitor to 1". Connect the negative lead of the capacitor to solder lug D (S-1). Place the 1-3/4" sleeve on the positive (+) lead and connect the lead to socket IC31 lug 1 (NS).
- () Prepare a 3" yellow wire.
- () Connect the 3" yellow wire from solder lug C (S-1) to IC31 lug 3 (NS).
- () C2: Cut one lead of a .22 μ F Mylar capacitor to 5/8". Connect this shortened lead to socket IC31 lug 3 (NS) and the longer lead to lug 1 (NS).
- () C3: Cut one lead of the other .22 μ F Mylar capacitor to 5/8". Connect this lead to socket IC31 lug 3 (S-3) and the longer lead to lug 2 (NS).
- () Prepare a 7-1/4" orange wire.
- () Connect one end of the 7-1/4" orange wire to socket IC31 lug 2 (S-2).
- () Prepare a 9" white-orange wire.
- () Connect one end of the 9" white-orange wire to socket IC31 lug 1 (S-3).

- () Cut a 2" piece of flat braid.
- () Refer to Detail 4-2A and crimp and solder a spade lug onto one end of the 2" braid. Apply a liberal amount of solder to 1/4" of the free braid end.
- () Loosely mount the support bracket to the foil side of the main circuit board at E with a 6-32 × 1/4" screw and a 6-32 nut. Secure the support bracket and the spade lug with the braid at F with a 6-32 × 1/4" screw and 6-32 nut. Be sure to position the free end of the braid as shown in the Pictorial. Tighten the support bracket mounting hardware.
- () Refer to the Pictorial and form the center of the braid and the spade lug as shown to be sure the braid will not come in contact with any of the other circuit board foils.
- () Refer to Detail 4-2B and add a liberal amount of solder to the indicated foil pad on the main circuit board. Be very careful not to form a bridge to other foils. Press the free end of the braid onto the top of this foil pad and heat it with the soldering iron until the solder melts into the braid. Hold the braid in place with pliers until it has cooled.

Detail 4-2C

- () Refer to Detail 4-2C and pass the tip of the cable tie through hole G in the support bracket making sure the rough side is facing upward. Then pass the tie across the rear of the bracket and back through hole H making sure the rough side is down. Pass the cable tie around capacitor C1 and push the tip of the tie through the other end retainer as shown. Pull the tie until it is tightly secure around the capacitor; then cut off the excess tie end.

Refer to Pictorial 4-3 (Illustration Booklet, Page 5) for the following steps.

- () Reposition the circuit board as shown.
- () Prepare the following wires:

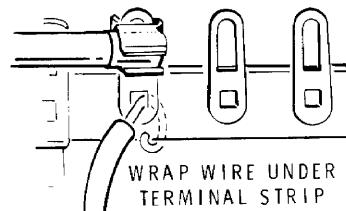

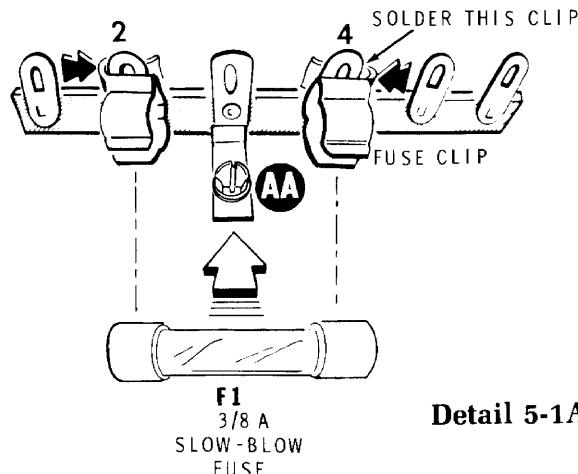

1-1/4" red	6-1/2" yellow
2-1/2" white-brown	6-1/4" white-yellow
2-1/2" brown	13" brown
1-3/4" orange	13" white-brown

NOTE: As you install wires in the following steps, form each of them as shown in the Pictorial. After a wire has been soldered to the foil or to the switch lug, cut off any excess wire lengths.

- () Connect one end of a 1-1/4" red wire to switch SW1 lug 1 (S-1). Slide a ferrite bead (#475-12) onto the free end of this wire; then connect the free end to the main circuit board hole R (S-1).

- () Connect a 2-1/2" white-brown wire from hole S (S-1) to switch SW1 lug 7 (S-1).
- () Connect a 2-1/2" brown wire from hole T (S-1) to switch SW1 lug 4 (S-1).
- () Connect a 1-3/4" orange wire from hole U (S-1) to switch SW1 lug 2 (NS). Be sure this wire does not cover the large nearby hole.
- () Form the orange wire coming from socket IC31 lug 2 downward and across the circuit board as shown. Connect the free end of the wire to SW1 lug 2 (S-2).
- () Route the free end of the white-orange wire coming from socket IC31 lug 1 downward to the board, and along the board as shown. Connect the free end of the wire to circuit board hole X (S-1).
- () Connect one end of a 6-1/2" yellow wire to circuit board hole W (S-1). Route the wire rearward, through support bracket grommet B. Connect the wire end to terminal strip C lug 1 (S-2).
- () Connect one end of a 6-1/4" white-yellow wire to circuit board hole V (S-1). Route the wire rearward, through support bracket grommet B. Connect the wire end to terminal strip C lug 2 (S-2).
- () Connect one end of a 13" brown wire to circuit board hole P (S-1). Route the wire forward, through support bracket grommet B. Connect the free end of the wire to switch SW1 lug 5 (S-1).
- () Connect one end of a 13" white-brown wire to circuit board hole N (S-1). Route the wire forward and through grommet B. Connect the free end of the wire to switch SW1 lug 8 (S-1).

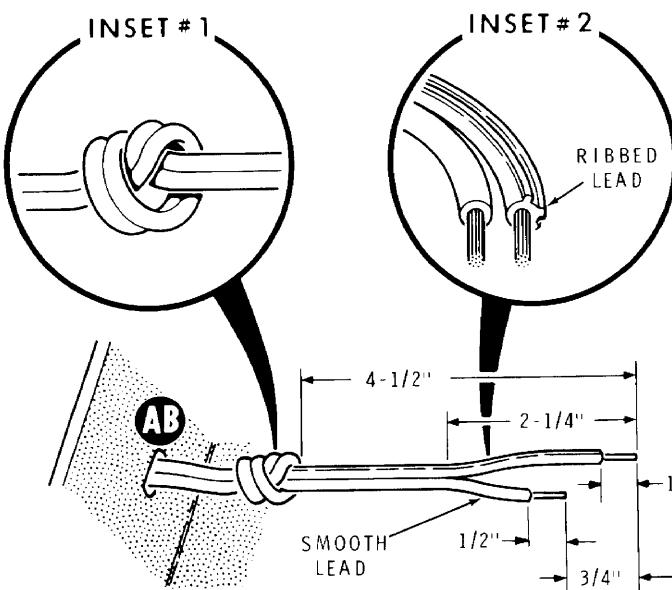

Set the main circuit board assembly aside temporarily.

CABINET ASSEMBLY AND WIRING.

Refer to Pictorial 5-1 (Illustration Booklet, Page 5) for the following steps.

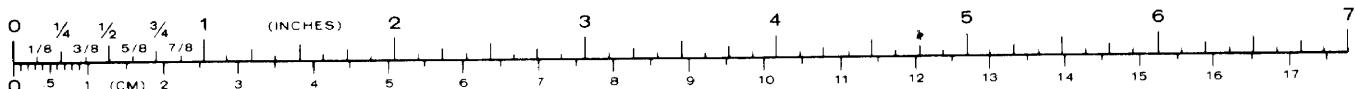

- () Temporarily mount a 6-lug terminal strip on cabinet post AA with a #6 x 3/8" hex head screw as shown.
- () F1: Refer to Detail 5-1A and install two fuse clips and the 3/8-ampere fuse on terminal strip AA lugs 2 and 4. Solder the fuse clip onto lug 4 only. NOTE: Do not use excessive heat to avoid damage to the fuse.

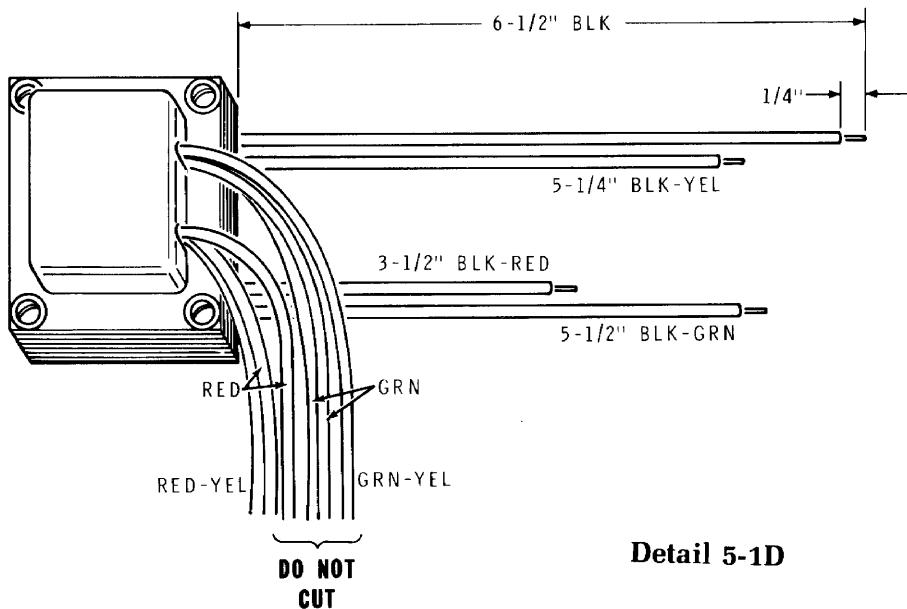

- () Refer to inset drawing #1 on Detail 5-1B and insert the end of the line cord through hole AB from the outside of the cabinet bottom. Tie a knot in the line cord 4-1/2" from the end as shown.
- () Refer to inset drawing #2 on Detail 5-1B and identify the smooth lead and the ribbed lead of the line cord. Then prepare the end of the line cord as shown in the Detail.
- () Tightly twist the bare wire ends and apply a small amount of solder to hold the fine strands together.

NOTE: As you connect the line cord leads in the following steps, be sure to make a mechanically secure connection. Wrap the lead ends securely under the terminal strip as shown in Detail 5-1C.

- () Smooth lead to the eyelet of lug 4 (S-1).
- () Ribbed lead to the eyelet of lug 6 (S-1).
- () Refer to Detail 5-1D and prepare the transformer leads as shown. Measure the leads from the edge of the transformer. If necessary, twist the lead ends tightly and apply a small amount of solder.
- () T1: Refer to Pictorial 5-1 and install the power transformer with the red and green leads up as shown. Use #6 x 1-1/8" self-tapping screws.

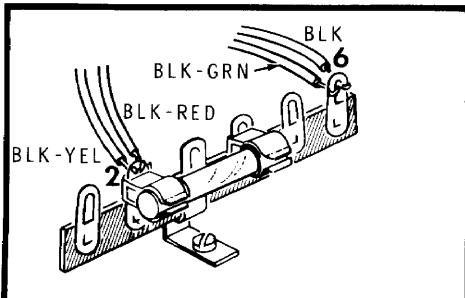

Detail 5-1D

ALTERNATE LINE VOLTAGE WIRING

Two sets of line voltage wiring instructions are given below, one for 120 VAC and the other for 240 VAC. In the United States, 120 VAC is most common. USE ONLY THE INSTRUCTIONS THAT AGREE WITH THE LINE VOLTAGE IN YOUR AREA.

FOR 120 VAC

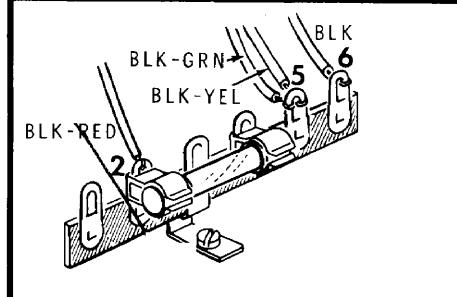

Detail 5-1E

Refer to Detail 5-1E for the following steps. In these steps, make connections to terminal strip AA. Wrap the lead ends tightly at the connections. Connect four of the power transformer leads as follows:

- () Black-red and black-yellow leads to lug 2 (S-2). NOTE: Also solder the fuse clip to lug 2.
- () Black-green and black leads to lug 6 (S-1).

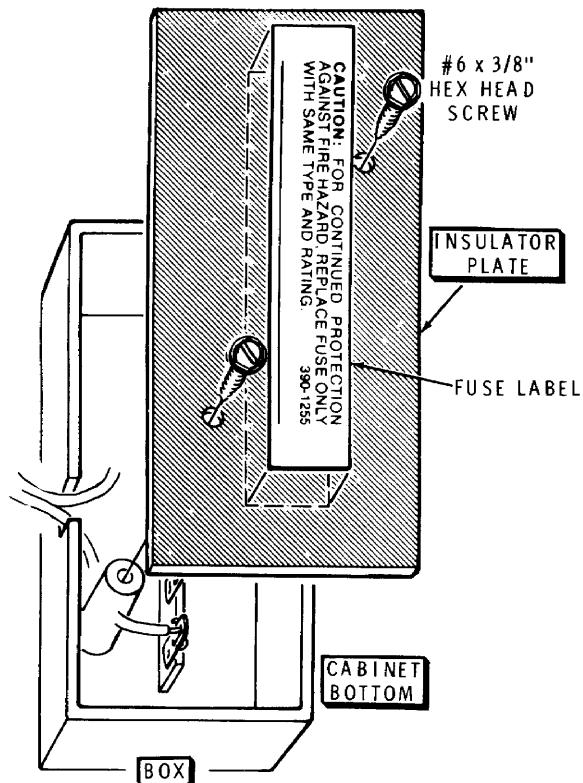

FOR 240 VAC

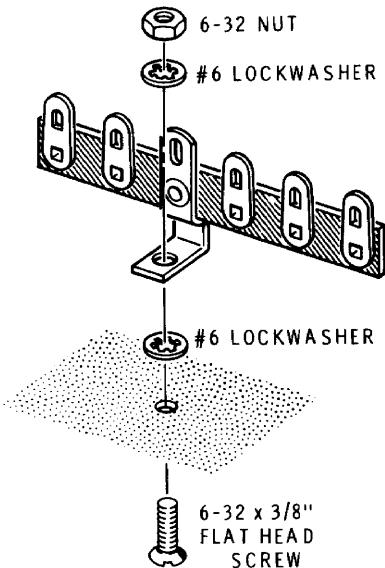

Detail 5-1F

Refer to Detail 5-1F for the following steps. In these steps, make connections to terminal strip AA. Wrap the lead ends tightly at the connections. Connect four of the power transformer leads as follows:

- () Black-red lead to lug 2 (S-1). NOTE: Also solder the fuse clip to lug 2.
- () Black-yellow and black-green leads to lug 5 (S-2).
- () Black lead to lug 6 (S-1).

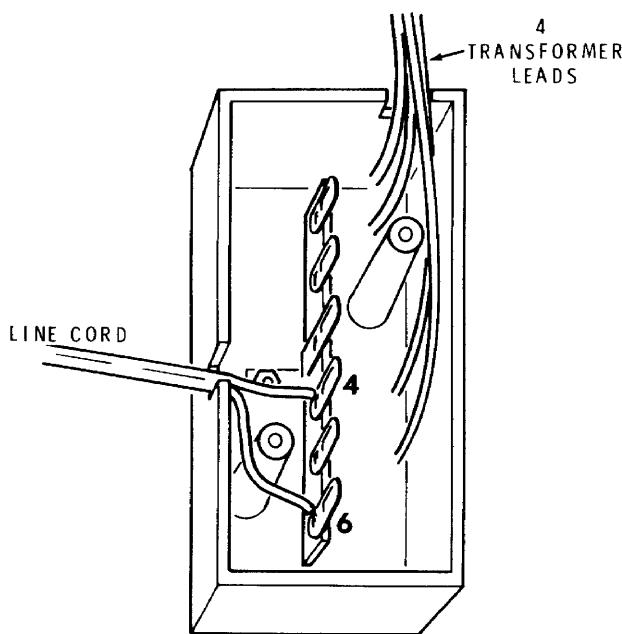

- () Remove the fuse from the fuse clips. Then remove the screw you used to secure the terminal strip to the cabinet post.

Detail 5-2A

- () Refer to Detail 5-2A and mount the terminal strip in the box formed in the cabinet bottom as shown. Use a 6-32 × 3/8" flat head screw, two #6 lockwashers, and a 6-32 nut. Position the terminal strip as shown in Detail 5-2B.
- () Reinstall fuse F1 in its fuse clips.

Detail 5-2B

- () Refer to Detail 5-2B and route the leads and wires as shown.
- () Mount the insulator plate to the terminal strip box with two #6 × 3/8" hex head screws. Do not pinch any leads between the plate and the box.
- () Remove the paper backing from the fuse label and press the label in place onto the insulator plate. Then write the fuse information on the label: "3/8-Amp, 3AG, slow-blow."

Again, refer to Pictorial 5-1 (Illustration Booklet, Page 5) for the following steps.

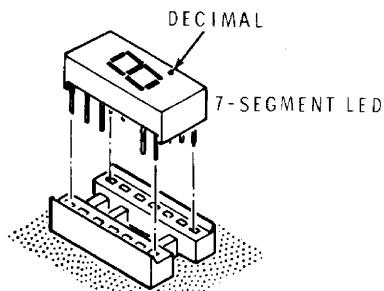

NOTE: As you connect each of the remaining power transformer wires to the main circuit board in the following steps, solder the lead to the foil and cut off the excess lead lengths.

- () Position the main circuit board, component side up, near the power transformer as shown in Pictorial 5-1.
- () Connect the red-yellow transformer lead to the circuit board hole labeled "RED/YEL."
- () Connect the green-yellow lead to the hole labeled "GRN/YEL."
- () Connect either red lead to one hole labeled "RED."
- () Connect the other red lead to the remaining "RED" hole.
- () Connect one green lead to one of the holes labeled "GRN."
- () Connect the other green lead to the remaining "GRN" hole.

NOTE: The remaining yellow wire is for any experiments you may want to do.

This completes the "Step-by-Step Assembly." Proceed to "Initial Tests."

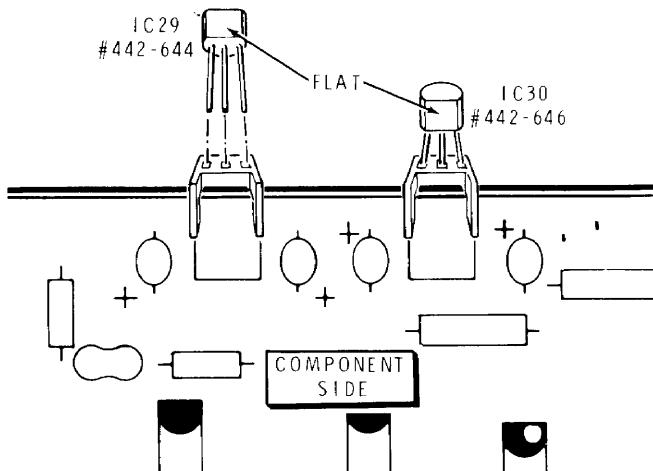

INITIAL TESTS

Detail 6-1A

Refer to Pictorial 6-1 (Illustration Booklet, Page 6) for the following steps.

- () Position the main circuit board part way out of the cabinet bottom as shown.
- () Refer to Detail 6-1A and carefully install a 7-segment LED at "H" in the manner shown.
NOTE: Be sure a decimal point is at the **bottom right** as shown in the Pictorial. (Do not shorten the leads. They act as heat sinks.)
- () In the same manner, install the remaining five 7-segment LED's at "I," "N," "Z," "V," and "C."
- () IC29: Refer to Detail 6-1B and carefully install the LM78L12 IC (#442-644) into the socket at IC29 in the manner shown.

Detail 6-1B

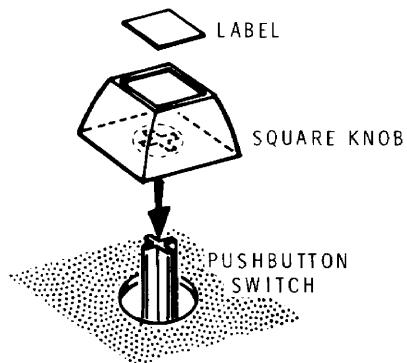

- () IC30: In the same manner, install the MC79L12AC IC (#442-646) in the socket at IC30.

VOLTAGE TESTS

NOTE: If at any time during the following tests you fail to obtain the desired results, and if power is applied to the unit, immediately unplug the line cord from the outlet and refer to the "In Case of Difficulty" section on Page 76.

You will need a volt-ohmmeter to perform the following tests. If such a meter is not available, proceed to "Tests Continued."

- () Connect one ohmmeter lead to one prong of the line cord plug, and the other lead to the remaining prong. The ohmmeter reading should be near or at zero.
- () Push down on the left side of the POWER switch (SW1) to be sure it is Off.
- () Plug the line cord into an AC outlet. The red LED next to the power switch should come on immediately and will remain on, regardless of the power switch setting.
- () Prepare two 1-1/2" wires. These may be of any color.
- () Locate the 4-pin connector blocks near the lower left corner of the circuit board labeled "+5" and "GND." Push one end of a short wire into each of these blocks.
- () Set your voltmeter to read +5 volts. Connect the positive lead to the wire at "+5" and the negative lead to "GND."
- () Push down on the right side of the POWER switch (SW1).
- () You should read 4.5 to 5.5 volts on the voltmeter.

**Detail 6-2A**

- () Set the voltmeter to read +12 volts. Move the positive meter lead and the test wire from "+5" to "+12." You should read 10.8 to 13.2 volts on the meter.
- () Remove the voltmeter leads from the test wires; then move the test wire at "+12" to "-12."
- () Connect the positive test lead to "GND" and the negative lead to "-12." You should read 10.8 to 13.2 volts on the meter.

This concludes the portion of the tests that require the use of the volt-ohmmeter. Set the meter and wires aside.

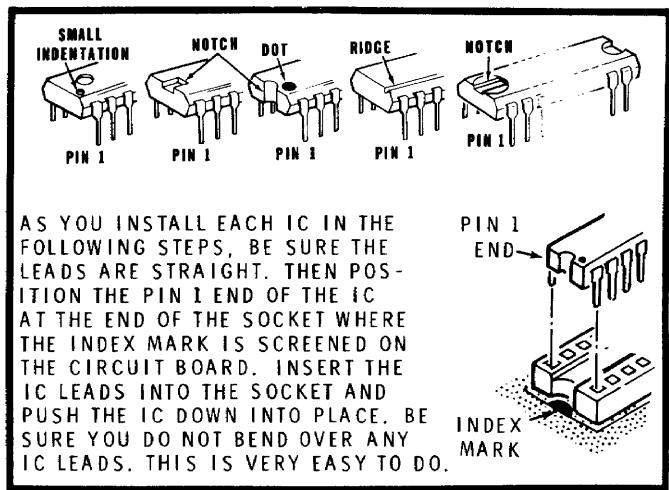

TESTS CONTINUED

- () If not already done, plug in the line cord and push down on the right side of the POWER switch (SW1). The red LED next to the POWER switch should turn on. (This LED will be on no matter which position the switch is in.)
- () At the right edge of the circuit board, locate the "SEGMENT TEST" pins. Short these two pins together and note that all seven segments on the 7-segment LED's are lit, as well as the decimal point at the lower right of each LED. (Some LED's may already be lit.)

- () Push the POWER switch to Off and remove the line cord plug from the AC outlet.

Refer to Pictorial 6-2 (Illustration Booklet, Page 7) for the following steps.

- () Refer to Detail 6-2A and place a square knob onto one of the pushbutton switches at the lower right portion of the circuit board. Push firmly on the knob to seat it onto the switch.
- () In the same manner, install the remaining 16 square knobs on the pushbutton switches.
- () Locate the keyboard label set. Then, one at a time, remove each of the numbered or lettered labels from the paper backing and press the label onto its correct pushbutton knob as shown in the Pictorial.
- () Locate the red label set. One at a time, remove the red labels from the paper backing, then position the label squarely over the 7-segment LED and press it in place. (You should have two labels left over.)

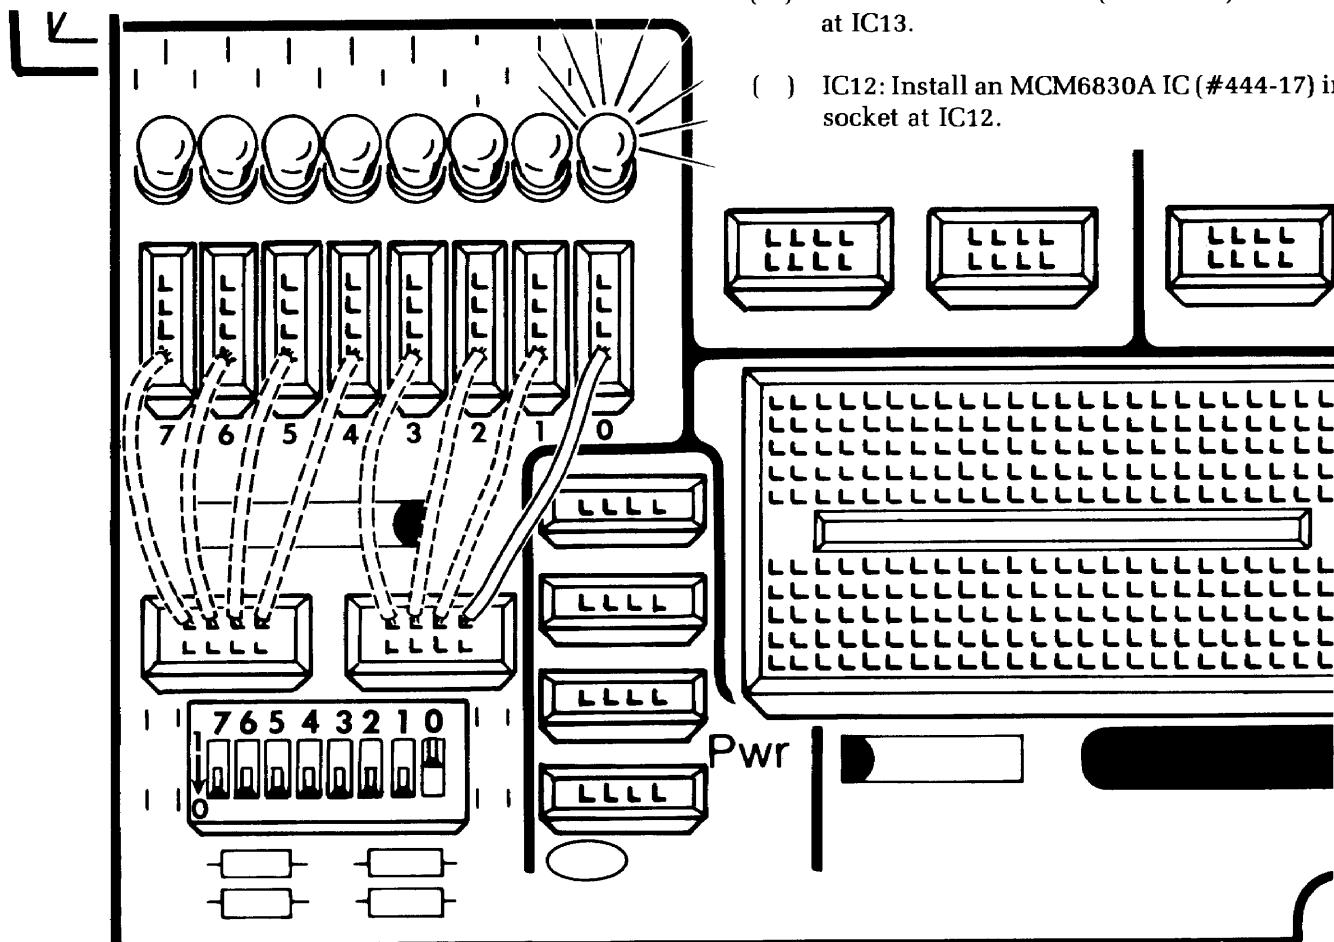

Detail 6-2B

NOTE: In the following steps, when you install an integrated circuit, refer to Detail 6-2B, remove the IC from its packing material (if necessary), and install the IC as shown.

Some of the IC's are packed in conductive foam. (Save this foam in case you ever remove these IC's.) These IC's are rugged, reliable components. However, normal static electricity discharged from your body through an IC pin to an object can damage the IC. Install these IC's without interruption as follows:

1. Remove the IC from its package with both hands.
2. Hold the IC with one hand and straighten any bent pins with the other hand.
3. Refer to Detail 6-2B. Position the pin 1 end of the IC over the index mark on the circuit board.
4. Be sure each IC pin is properly started into the socket. Then push the IC down.

- () IC14: Install a 2112-2 IC (#443-721) in the socket at IC14.
- () IC15: Install a 2112-IC (#443-721) in the socket at IC15.
- () IC13: Install a 40097 IC (#443-720) in the socket at IC13.
- () IC12: Install an MCM6830A IC (#444-17) in the socket at IC12.

Detail 6-2C

- () IC11: Install an MC6800P IC (#443-827) in the socket at IC11.
- () Prepare a 4" yellow wire.
- () Plug in the line cord and turn the Trainer on.

Refer to Detail 6-2C for the following three steps.

NOTE: In the following steps, you will check out the Binary Data LED's at the lower left side of the circuit board. Each of these LED's is numbered (from right to left), directly beneath their corresponding 4-pin connector blocks, from "0" to "7." In addition, these connectors and LED's have corresponding switches on the slide switch assembly and pairs of connector pins in the two 8-pin connector blocks located immediately above the slide switch assembly.

- () Connect the 4" jumper wire from 4-pin connector block No. "0" to 8-pin block pair "0" (as shown on the Detail). Operate slide switch "0" and observe that the furthest right (zero) LED turns on and goes out.
- () Move the jumper wire to the "1" connector blocks, second from the right. Operate the slide switch and observe that the "1" LED turns on and goes out.
- () Progressively, and in the same manner, move the jumper wire to the "2," the "3," the "4," the "5," the "6," and the "7" connector blocks. Each time, operate the corresponding slide switch and observe that the correct LED is lit. Then remove the wire.

OPERATIONAL TESTS

This section of the Manual will check the basic Microprocessor functions to make sure they are working properly. The entries that will be made on the keyboard are not necessarily related to the actual use of the unit. Actual use of each function is explained in detail in the "Operation" section, starting on Page 45.

Refer to Pictorial 6-3 (Illustration Booklet, Page 7) to identify the function of each keyboard key.

NOTE: If you encounter any trouble in the following steps, turn the power off and remove the line cord plug from the AC outlet. Then refer to the "In Case of Difficulty" section on Page 91.

Each number step in the following charts shows which number or letter key to push, and what the resultant readout will be. Always push the keys in the sequence shown.

The following abbreviations are used on the Microprocessor keyboard:

ACCA	Accumulator "A"
ACCB	Accumulator "B"
PC	Program Counter
INDEX	Index Register
CC	Condition Codes Register
SP	Stack Pointer
RTI	Return From Interrupt
SS	Single Step
BR	Break Point
AUTO	Automatic Load
BACK	Back
CHAN	Change
DO	Do
EXAM	Examine
FWD	Forward

NOTES:

1. In the following charts, the symbol "*" is used to denote a blank readout indication. The symbol "X" indicates a random figure.
2. When you make two-digit entries, the indicated Readout display will be shown after the second digit key has been released.
3. If you make an incorrect entry, return to step 1.

STEP	FIRST PRESS:	THEN PRESS:	READOUT **
1	RESET		CPU * UP.
2	EXAM E		— — — Ad.
3		0 1 ACCA ACCB PC 2 3	0 1 2 3 XX
4	CHAN C		0 1 2 3 _ _
5		INDEX 4 CC 5	0 1 2 3 4 5
6	EXAM E		— — — Ad.
7		SP 6 RTI 7 SS 8 BR 9	6 7 8 9 XX
8	CHAN C		6 7 8 9 _ _
9		AUTO A BACK B	6 7 8 9 Ab
10	EXAM E		— — — Ad.
11		CHAN C DO D EXAM E FWD F	C d E F XX

** Shows readout as presented on LED's after the key is pressed.

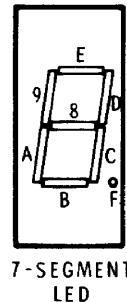

You have now determined that the Microprocessor keys are operating properly. Continue the operational test as you enter the following simple program.

STEP	FIRST PRESS:	THEN PRESS:	READOUT
1	RESET		CPU * UP.
2	AUTO A		----- Ad.
3		0 0 0 0 (Memory address)	0000
4	SS 8 6	(Load Accumulator A w/following two characters)	0001
5	0 ACCA 1	(Data for first step)	0002
6	BACK B RTI 7	(Store Accumulator A at extended address of following four characters)	0003
7	CHAN C ACCA 1		0004
8	SP 6 FWD F		0005
9	RTI 7 EXAM E	(Jump to extended address of following four bytes of information)	0006
10	0 0		0007
11	0 0		0008
12	RESET	(To terminate AUTO addressing sequence)	CPU * UP.
13	DO D		----- d o.
14		0 0 0 0	* * * *
15	RESET		CPU * UP.

The preceding program entered information into memory storage that told the Microprocessor that you wished to turn on the decimal point of the "H" LED. The program was proved in steps 13 and 14 above.

Note in step 8 the characters "6F." This is the information that told the Microprocessor that you wished to address the "H" LED, and in particular, the decimal point; the "6" addressed the LED and the "F" addressed the decimal point. Refer to Detail 6-3A and note that each segment of an LED may be similarly addressed. Thus, to turn on each segment of the "H" (or "6") LED in turn, the terminal character must be changed to agree with the segment address.

Detail 6-3A

In the following chart, the top bar of the "H" LED will be addressed and examined.

STEP	FIRST PRESS:	THEN PRESS:	READOUT
1	RESET		CPU * UP.
2	EXAM E		— — — Ad.
3		0 0 0 4 INDEX	0 0 0 4 6 F
4	CHAN C		0 0 0 4 _ _
5		SP 6 EXAM : "H" LED, TOP BAR.	0 0 0 4 6 E
6	RESET		CPU * UP.
7	DO D		— — — d o.
8		0 0 0 0	— * * * *
9	RESET		CPU * UP.

As you observed in step 8, only the top-bar segment of the "H" LED lit up. You may further address and call up the remaining segments, in turn, of the same LED as follows: Repeat all nine steps in the preceding chart, with **one** exception. After you push the "CHAN/C" key in step 4, enter "6D"; then proceed with the remaining steps 6 through 8. The next time, at step 5, enter "6C", and proceed. In the same manner, at step 5 of each repetition, enter "6B, 6A, 69 and 68." Refer to Detail 6-3A to determine which LED segment should be lit.

To address the individual segments of the "I" LED, use the preceding chart and perform steps 1 through 4 as before. At step 5, enter "5F," and proceed with steps 6 through 8. Note that the decimal on the "I" LED will light. Then, at step 5, one at a time, enter "5E, 5D, 5C, 5B, 5A, 59, and 58." All segments of the remaining four LED's may be called up in a like manner using, for example: "4F, 3F, 2F, 1F" at step 5 to light the respective decimal segments.

This completes the "Operational Tests" of your Microprocessor Trainer.

NOTE:

Provision has been made for you to install a 40-pin connector for system expansion. Brief instructions

and a list of manufacturers are given below. If you do not wish to install a connector at this time, proceed directly to "Final Assembly" on Page 42.

Purchase and install a 40-pin connector* on the circuit board between IC2 and IC3. Then connect eight wires from the eight circuit board holes that connect the connector data pins to the eight data holes near IC9 and IC10. (See the "Schematic" and "Circuit Board X-Ray View.") These wires connect the eight data lines (D0-D7). Be sure you connect these wires properly so that data D0 goes to data line D0, etc.

*The connectors must have .025" square pins on .100" centers. The following manufacturers supply such connectors. Some are single strips of connectors that must be cut to length.

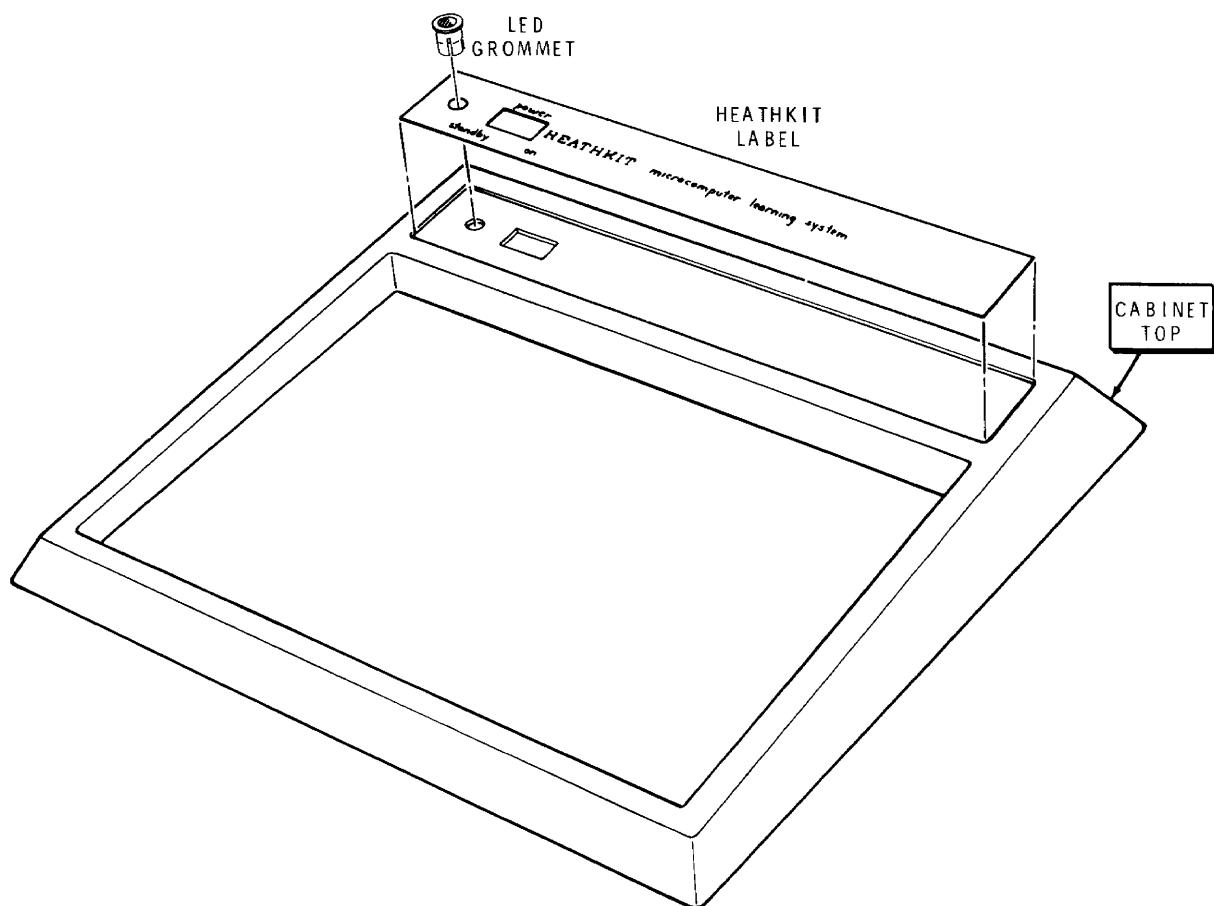

AP Products
929834-01 (2 strips required)
929836-01

Molex
22-04-2201 (2 strips required)

AMP
2-87215-0
2-87543-0

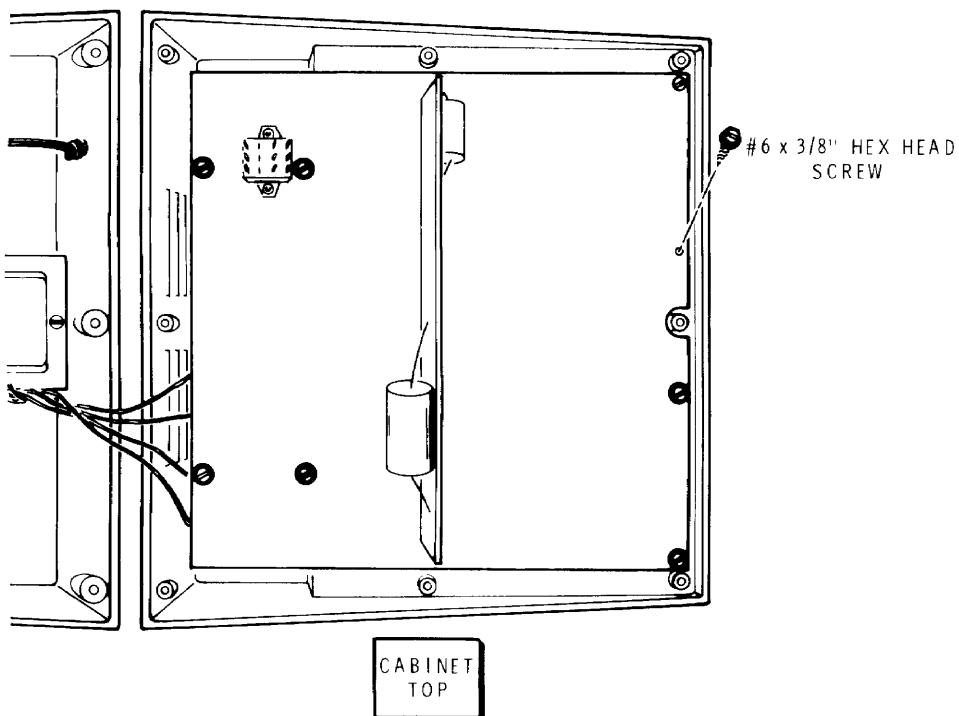

FINAL ASSEMBLY

PICTORIAL 7-1

Refer to Pictorial 7-1 for the following steps.

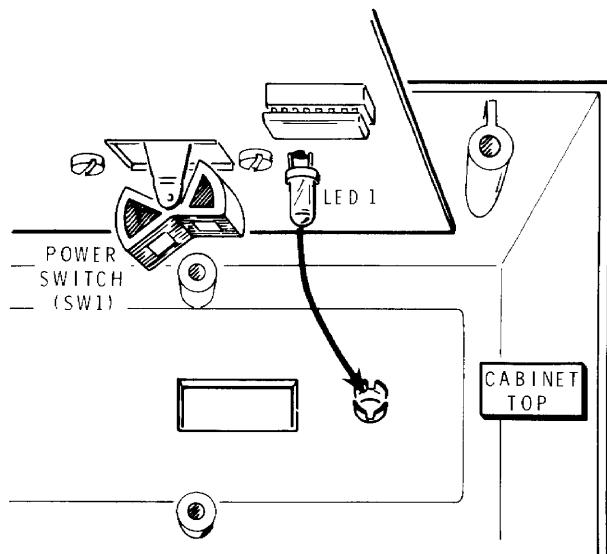

- () Remove the paper backing from the "Heathkit" label. Carefully press the label in place on the upper portion of the cabinet top as shown.
- () Press an LED grommet into the small round hole in the cabinet top.

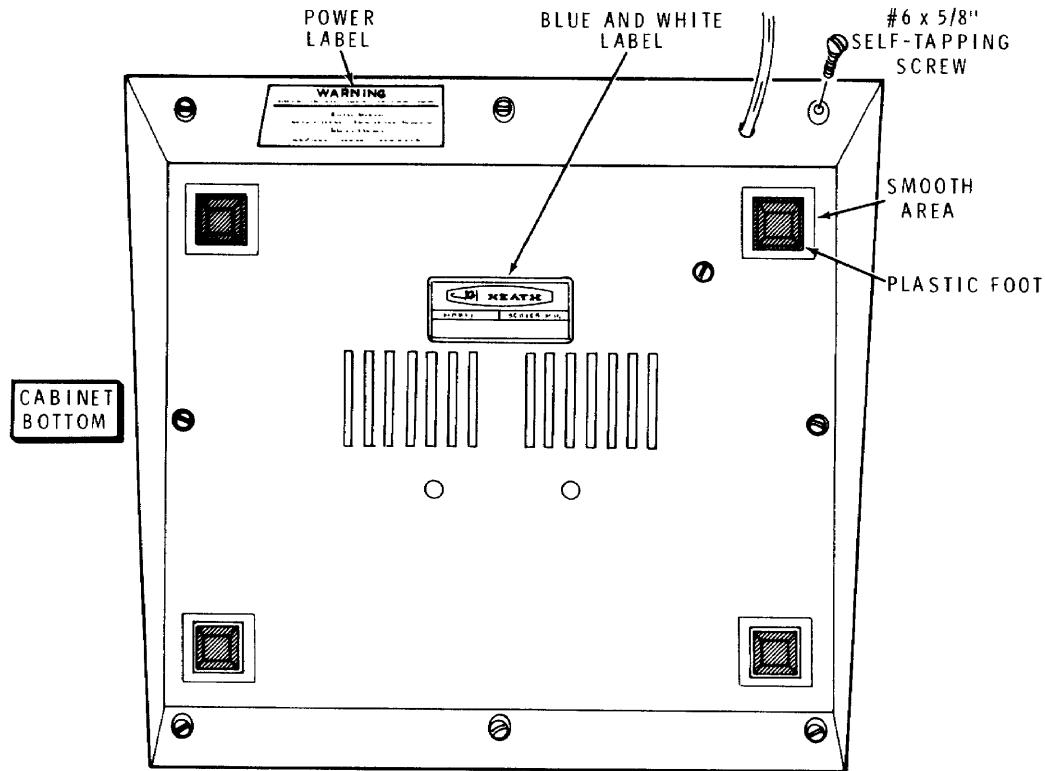

PICTORIAL 7-2

Refer to Pictorial 7-2 for the following steps.

- () Unplug the line cord.
- () Turn the cabinet top upside down and position it near the cabinet bottom as shown in the Pictorial. As you lower the main circuit board down onto the inverted cabinet top, be sure that LED1, next to the Power switch, fits straight down into the LED grommet as shown in Detail 7-2A. NOTE: If the LED protrudes through the cabinet top too far, resolder the LED's leads so the LED is closer to the circuit board.
- () Secure the main circuit board to the cabinet top with eight #6 × 3/8" hex head screws.

Detail 7-2A

**PICTORIAL 7-3**

Refer to Pictorial 7-3 for the following steps.

- () Turn the cabinet top and main circuit board assembly right side up and fit the assembly into the cabinet bottom.
- () Turn both cabinet halves bottom-side up as shown in the Pictorial; then secure the bottom to the top with eight $\#6 \times 5/8"$ self-tapping screws.
- () Remove the paper backing from the four feet and press them in place on the cabinet bottom in the smooth areas near the four corners as shown.

- () Remove the paper backing from the blue and white label and press the label in place on the cabinet bottom. NOTE: Be sure to refer to the numbers on the blue and white label in any correspondence you have with the Heath Company about your kit.
- () Remove the paper backing from the power label and press the label in place near the line cord as shown in the Pictorial.

This completes the "Final Assembly" of your kit. Proceed to "Operation."

OPERATION

This section of the Manual describes the operation of your Trainer, explains the keyboard commands, describes how to enter programs, has several sample programs, contains the monitor listing and several subroutine flowcharts, shows the memory map, and lists the entire 6800 instruction set.

Pictorial 8-1 (Illustration Booklet, Page 8) gives a brief description of the switches, LED's, and connectors.

KEYBOARD

The keyboard allows you to quickly enter commands and data to the microprocessor. After you press the RESET key, the display will show CPU UP, and the next keyboard entry will be interpreted as a command. The following paragraphs discuss the various commands.

Display Accumulator A

1 Press this key and the contents of accumulator A will be displayed. The first four digits and decimal point identify the display, and the next two digits show the contents of the accumulator.

In the following example, the contents of accumulator A is $4A_{16}$ (or binary 01001010).

Example: Acca.4A

Now you may change the contents of accumulator A if you wish. To do this, press the **C** key. The display will now be:

Acca. - -

With two key strokes, enter the new hexadecimal number you want in accumulator A.

Display Accumulator B

2 Press this key and the contents of accumulator B will be displayed. A typical display is:

Accb.5F

In this example, accumulator B contains $5F_{16}$ (binary 01011111).

The contents of accumulator B can be changed in the same way that accumulator A is changed.

Display Program Counter

3 Press this key and the contents of the microprocessor's program counter will be displayed. The first two digits and decimal point identify the display, and the next four digits show the contents of the program counter.

Example: Pc.0040

In this example, the program counter contains 0040_{16} . You may change the program counter by pressing the **C** key and then entering the new hexadecimal number.

Display Index Register

4 Press this key and the contents of the index register will be displayed.

Example: In.FDF4.

You can change the register by pressing the **C** key and then entering a new hexadecimal number.

Display Condition Codes Register

5 Press this key and the contents of the condition codes register (1's and 0's) will be displayed. The display letters (H, I, N, Z, V, and C) correspond to the letters assigned to the six condition codes. (See the "instruction set" on Page 89.)

Example: 001001

This register **cannot** be changed by pressing the **C_{CHAN}** key.

Display Stack Pointer Register

6 Press this key and the contents of the stack pointer register will be displayed.

Example: SP.00d2

This register **cannot** be changed by pressing the **C_{CHAN}** key.

Resume User's Program

7 Press this key and your program will start at the location contained in the program counter. This key is used to return to normal user program operation from breakpoints or single stepping.

Single Step User's Program

8 Press this key and the microprocessor will perform only one step of your program. The instruction to be performed is taken from the address contained in the program counter. After the step, the next instruction and its address are displayed. The displayed instruction may be changed by pressing the **C_{CHAN}** key and then entering the new data. Also at this time, you may examine registers, memory, or use any of the other monitor functions.

Set Breakpoint

9 Press this key and you can then make an entry into the monitor breakpoint table. A breakpoint is a point where you want to stop the program to examine the microprocessor registers, memory, etc.

The display is _____ br.

Enter the four digits of a hexadecimal address for the breakpoint. The address must be the address of an operational code in your program and that code must be in RAM. No breakpoints are possible in ROM. You may have up to four breakpoints in your program at any one time.

Do not press the RESET key. This clears all the breakpoints.

If you make an incorrect entry, and the entry is still displayed, press the **C_{CHAN}** key as many times as necessary for the display to return to _____ br. Then enter the correct address.

Auto Load Of Memory

A_{AUTO} Press this key and _____ Ad will be displayed.

Enter the address you want to start at. Example: Enter 0, 0, A, and 4. The display is now:

00A4 ____.

Enter the 2-digit hexadecimal value you want entered at that address.

The display will now advance to the next address. You can continue changing memory data until you press the RESET key.

Display Previous Address

B_{BACK} Press this key when an address and its data are displayed (you are examining memory with the E function, your program has come to a breakpoint, or you are single stepping your program), and the previous address and its data will be displayed. You may change this data by pressing the **C_{CHAN}** key and then entering the new data.

Change Displayed Value

C Press this key when an address and its data are displayed, and the data will be replaced with “_”. Then enter the new hexadecimal value you want at this address.

You may use this function to correct a value you entered by mistake. However, if the monitor is expecting a command and the change function is not valid, the change command will be ignored.

DO User Program

D Press this key and the display will become:
— — — do.

Enter the beginning address of your program. Your program will now start at the new address instead of where the program counter was pointing. The display will become blank and the program will run until a display is called for, until it comes to a breakpoint, or until you press the reset key.

This key function combines several other functions. You could get the same result by displaying and changing the program counter and then pressing the **RST** **7** key.

Examine Memory

E Press this key and the display will become:
— — — Ad.

Enter a new address. The display will now indicate the data at this new address. You may now change the displayed value by using the **C** key or you can step backwards or forwards through memory using the **BACK** **B** and **FWD** **F** keys.

Display Next Address

F Press this key when an address and its data are displayed, and the next address and its data will be displayed. You may change this data by pressing the **C** key and then entering the new data.

ENTERING PROGRAMS

Pictorial 8-2 shows the first two instructions of Sample Program 1 (in the following section) and indicates the various information they contain. This information is further described in the following paragraphs.

Instruction Address: This is usually called the Program Counter. In order to perform an instruction, the Program Counter must contain the address that is in this column. RTI and SS require the Program Counter to contain the address that is in this column for proper execution. The address entered after DO is pressed must be an instruction address. Breakpoints are not recognized except at instruction addresses.

Instruction: This is one, two, or three bytes of data as required by the addressing mode used.

Op code: This is a ‘byte of information referred to as machine code, it indicates in hexadecimal the operation to be performed.

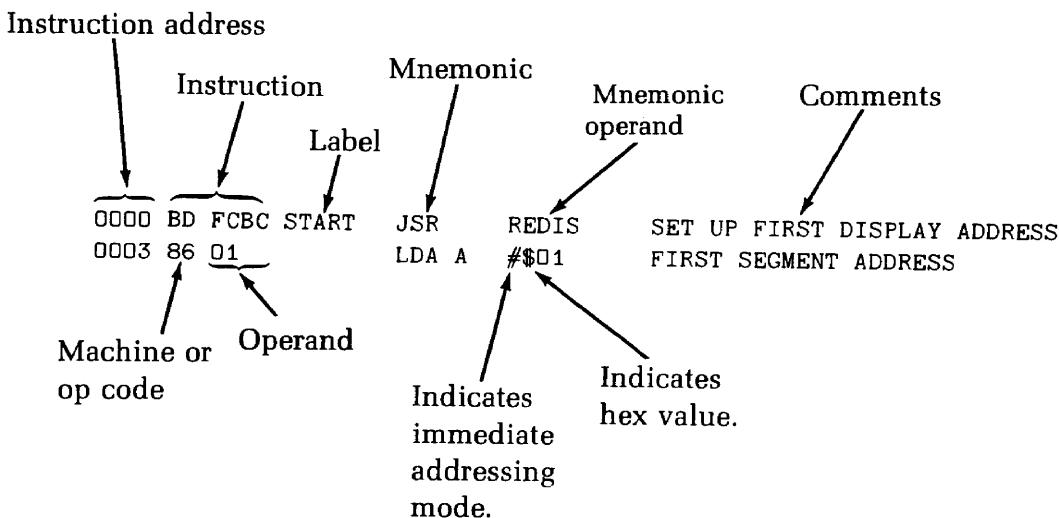

Operand: This is additional hexadecimal information required to perform the operation. It may be zero, one, or two bytes as determined by the addressing mode.

Label: This is usually a name applied to a subroutine in the program used more than once. In the sample programs, the address to be entered to begin execution is labeled “Start.”

Mnemonic: This is a three-letter indication of the source instruction. A fourth letter, A or B, is added to indicate which of two accumulators if the instruction applied to either one.

Mnemonic operand: Again, this is additional information that is required for the operation. It may be a label, address, or data. The \$ sign indicates the information is a hex value. The # sign indicates the immediate addressing op code is to be used.

Comments: This is a brief description of what is happening in the program.

PICTORIAL 8-2

When you load a program into the Trainer, only the one, two, or three bytes of each instruction are entered. You may use either of two modes to enter the instructions: "Auto", or the more laborious "Examine and Change." Forward, Back, and Change are valid commands in the Examine, and Change mode and may be used to correct entry errors. However, they are not valid in Auto. If you make an error in the Auto mode, press the Reset and Auto keys. Then enter the address where the error was made and continue from there; or, remember where the error was made and then examine and change that memory location after you finish entering the entire program.

The following charts show the sequence of events to enter the first two instructions of sample program 1. The first chart shows the Examine and Change mode while the second chart shows the Auto mode.

Examine and Change

Press the EXAM key and then enter the first instruction address, 0000, by pressing the 0 key four times. Then check the display and continue to enter the program as shown below.

Display is	→	Press	→	Enter	→	Display is	→	Press >
0000XX		CHAN		BD		0000BD		FWD
0001XX		CHAN		FC		0001FC		FWD
0002XX		CHAN		BC		0002BC		FWD
0003XX		CHAN		86		000386		FWD
0004XX		CHAN		01		000401		FWD
0005XX		CHAN		etc.				

Auto

Press the AUTO key and then enter the first instruction address, 0000, by pressing the 0 key four times.

Display → Enter
is

0000--	BD
0001--	FC
0002--	BC
0003--	86
0004--	01
0005--	etc.

Press RESET after last entry to exit the AUTO mode.

If Examine and Change is used, the last entry in sample program 1 (Page 55 and last page of Illustration Booklet) results in the display 0025 DA, and this display remains until a new command is entered through the keyboard.

If Auto is used, the last display will be the address of the next continuous memory location which is the last program instruction address plus the number of bytes in the instruction. In this program, 0024 plus two; 0026_. The dash (or "prompt" characters) are displayed in the data locations.

After you enter a program, by either method, check the ending address to be sure that you have not omitted or double entered data.

Enter sample program 1 (on Page 55 and last page of Illustration Booklet) into your Trainer. Use either of the two entry methods.

If you used the Examine and Change mode to enter the program, the program can be run by pressing DO and entering the address of the instruction labeled "Start," 0000. If you used the Auto mode, first press the RESET key to exit the Auto mode. Then press DO and enter the address of the instruction labeled "Start," 0000.

USING BREAKPOINTS

We will now use sample program 1 to show how programs can be inadvertently changed and even "crash" when breakpoints are inserted at improper locations (at addresses other than the instruction address).

Press RESET and insert breakpoints at 0004 and 0005.

Press BR 0004.

Press BR 0005.

Start the program by pressing DO 0000.

Notice that the CPU has ignored the breakpoint at 0004 and stopped at 0005.

Examine 0003 and 0004 by pressing EXAM, 0003, and FWD. The instructions there are correct (86 and 01).

Examine accumulator A by pressing the ACCA key.

Accumulator A has been loaded with the software interrupt instruction 3F that was temporarily placed at 0004 by the breakpoint at that address.

Watch the "H" display and press RTI. The 3F in accumulator A caused the first display to be incorrect. The program will stop again at 0005.

Insert a breakpoint at 0002 and then press RTI to resume execution. The program will run until it comes to 0002 which is changed by the breakpoint to 3F. The program will "crash" because of the wrong instruction and one of three things will happen: The display will be blank; all eights will be displayed; or all eights will appear, followed by CPU UP. In any case, press Reset to return control to the monitor program.

Press EXAM and enter 0000. Use FWD and CHAN to examine and correct errors introduced when the program crashed. You will always find the data at the breakpoint addresses has been changed. More often than not, the data at the breakpoint addresses will become 3F, although this may also change because the program crashed. Before you proceed, run the program to be sure all errors have been corrected.

In order to properly execute SS or RTI, the program counter must contain the instruction address where you wish to start. If single step begins at an incorrect address, the single step routine will not execute an invalid instruction and the display will not change. If the instruction at the PC address is a valid opcode, SS will execute the instruction using the following bytes as necessary and will continue unless it comes to an invalid instruction. RTI will try to execute the instruction in the same manner; except in the case of an invalid instruction, the program will probably crash. We will use SS to illustrate what happens.

Push RESET. Examine the Program Counter by pushing PC. Then change it to 0016 by pushing CHAN and 0016.

Press SS. The instruction at 0016 is not a valid instruction. In the single step mode, the machine will reject the instruction and 0016 FD will continue to be displayed and nothing happens. If RTI is pressed, the program will crash as it would when an invalid instruction is encountered. Probably only the first in-

struction will be changed, if any, in this particular circumstance. If you press RTI to see what happens, examine the program afterwards and correct any errors introduced; then run the program to be sure it is correct before proceeding.

Examine and change the program counter to 000F by pressing PC, CHAN, and 000F. Press SS. In this case FE is a valid instruction, LDX extended, and X is loaded from non-existent memory locations 3ACE and 3ACF.

Press SS. Here again 2F is a valid instruction (a conditional branch BLE). A branch may occur to 0015 or the program may fall through to 0014. In either case, two incorrect instructions have been performed in place of two or three correct instructions introducing error in the program. This is of no great consequence in this program but may be in another. Since an invalid instruction was not encountered, placing the program counter at 000F and pressing RTI would do exactly the same thing.

Now sample program 1 will be used to illustrate a procedure using breakpoints and single step to go through a program.

There are two important considerations pertaining to reserved memory bytes to keep in mind. First; DIGADD is used by all monitor routines. If you examine

these memory locations, 00F0 and 00F1, you will always find C12F, "V" display address, there because the examine command puts it there before it outputs the data. Secondly; DIGADD is always loaded with C16F, "H" display address, when DO or RTI are used.

Single step uses RMB TEMP, T1 and T0 in common with many of the monitor routines. Single step will replace information stored at these locations by the monitor routines. As a result, the routine may return with incorrect information or it may not be able to return at all and the program will crash.

When the program stops, at a breakpoint or after a single step, the address of the next instruction (contained in the program counter) and the instruction will be displayed. You may examine and make changes to any register (except stack pointer) or address provided you DO NOT change the program counter. The instruction displayed when the program stopped will be the next one executed when SS or RTI is pressed, regardless of what is being displayed.

The following procedure gives instructions. The six characters on the right, on the same line, indicate what the display should be after you perform the instruction. You will be instructed to examine registers affected by the instruction that has been executed.

You may examine any other registers or memory locations if you wish. The comment after an instruction is explanatory information.

<u>INSTRUCTION</u>	<u>DISPLAY</u>
Press RESET.	CPU UP.
Press PC, CHAN, and enter 0000. The program counter now contains the start address.	Pc 0000
Press SP. This is the next location available on the stack. The JSR instruction should store the address for return from the REDIS subroutine (0003) at this location.	SP 00d2
Press SS, Jump to REDIS.	FCbC dF
Press EXAM and 00D1.	00d1 00
Press FWD. Return address is on stack.	00d2 03
Press BR and enter 0003. To get past monitor routine.	0003 br
Press RTI. Might normally use examine to check result of routine. In this case, DIGADD RMB is loaded with C16F. Examine will just change what is there.	0003 86
Press SS.	0005 20
Press ACCA. (A) loaded with correct value.	Acca.01
Press SS. Branch to OUT-offset correct.	000E bd
Press SS. Jump to OUTCH.	FE3A dF
Press BR and enter 0011. To get past monitor routine. Could check stack here if desired.	0011 br
Press RTI. Exit OUTCH address of next display in DIGADD; Do not check.	0011 CE
Press SS.	0014 09
Press INDEX. Is (X) loaded?	In.2F00
Press SS.	0015 26
Press INDEX. Is (X) decremented?	IN.2EFF
Press CC. Z bit clear if (X) not 0000 yet.	XXX0 XX (X = don't care)
Press SS. Branches to WAIT if Z was clear.	0014 09
Press INDEX, CHAN, and enter 0001.	In.0001
Press SS.	0015 26

Press CC. (X) decremented to 0000 sets Z bit. Should drop through branch now.	XXX1 XX
Press SS. It did.	0017 16
Press ACCA.	Acca.01
Press SS.	0018 5d
Press ACCB. What was in (A) should be in (B).	Accb.01
Press SS.	0019 26
Press CC. Z bit clear if (B) not 00.	XXX0 XX
Press SS. Branches to SAME if Z is clear.	0007 d6
Press SS.	0009 Cb
Press ACCB. When the program runs normally, (B) at this point would be 5F because exit from OUTCH would be with the next display address, C15F, in DIGADD. Single step has caused DIGADD to be C10F.	Accb.0F
Press SS.	000b d7
Press ACCB. Hex 10 has been added to (B).	Accb.1F
Press SS. (B) has been stored at DIGADD. No reason to examine 00F1 since EXAM and SS will change what is there anyway.	000d 48
Press ACCA.	Acca.01
Press SS.	000E bd
Press ACCA. ACCA was 0000 0001 binary (01 hex). It has been shifted left and is now 0000 0010 binary (02 hex). The program is back to jump to OUTCH again. The same method as used before would get you back 0019 again. The program has proven good to that point so we will use a different method.	Acca.02
Press Reset. This clears the previous breakpoints.	CPU UP
Press BR and enter 0018.	0018 br.
Press DO and enter 0000. You may have noticed the program ran up to the breakpoint and the counter segment in "H" was momentarily lit. Now you are in another loop. You could press RT1 seven times and go back through the loop until (B) is 00. Again, since the branch is operating properly it is easier to change (B) to 00 and continue.	0018 5d
Press ACCB, CHAN, and enter 00.	Accb.00

Press SS.	0019 26
Press CC. The Z bit is set and the program should fall through the branch.	XXX1 XX
Press SS. It did.	001b 86
Press SS.	001d de
Press ACCA. (A) is loaded correctly.	Acca.01
Press SS.	001F 8C
Press Index. This is DIGADD again. Although the program has just finished with the "H" display, single step has placed C10F in DIGADD. This happens to be the address that will be in DIGADD after DP goes out in the "C" display and should result in a branch back to START.	In.C10F
Press SS. Same conditional BRANCH.	0022 26
Press CC. Z is set and the program should fall through.	XXX1 XX
Press SS. It did.	0024 20
Press SS. Every instruction in the program has been run except for the conditional branch at 0022.	0000 bd
Press Reset. Clears the breakpoint at 0018	CPU UP
Press BR and enter 001F.	001F br
Press DO and enter 0000.	001F 8C
Press Index. This time the program runs straight through until after (X) is loaded from DIGADD (at 001D) without an intervening single step or breakpoint. All segments were turned on and off in the "H" display and "I" display address C15F is in the index register as it should be.	In.C15F
Press SS. Conditional branch.	0022 26
Press CC. Z is clear and a branch to out should take place.	XXX0 XX
Press SS. It did.	000E bd
The entire program has now been run.	

SAMPLE PROGRAMS

These sample programs will give you practice entering programs and show the use of Monitor subroutines.

SAMPLE 7

THIS PROGRAM CALCULATES THE OP CODE VALUE FOR BRANCH INSTRUCTIONS USING THE LAST TWO DIGITS OF THE BRANCH AND DESTINATION ADDRESSES. THE BRANCH ADDRESS IS ENTERED FIRST AND DISPLAYED AT "H" AND "I". THE DESTINATION ADDRESS IS THEN ENTERED AND DISPLAYED AT "N" AND "Z". THE OP CODE IS THEN CALCULATED AND DISPLAYED AT "V" AND "C". THE DISPLAY IS HELD UNTIL NEW INFORMATION IS ENTERED. SINCE ONLY TWO DIGITS ARE ENTERED, IT IS NECESSARY TO MAKE AN ADJUSTMENT IF THE HUNDREDS DIGIT IN THE TWO ADDRESSES IS NOT THE SAME. FOR EXAMPLE TO CALCULATE THE OFFSET OF A BRANCH FROM 00CD TO 011B. SUBTRACT A NUMBER FROM BOTH ADDRESSES THAT WILL MAKE THE GREATER ADDRESS LESS THAN 100. FOR EASE OF CALCULATION IN THIS CASE, SUBTRACT C0 FROM BOTH ADDRESSES AND ENTER THE RESULTS 0D AND 5B IN THE PROGRAM. SINCE THE DIFFERENCE BETWEEN THE ADDRESSES IS UNCHANGED THE CORRECT OP CODE (4C) WILL BE DISPLAYED. IF THE DISTANCE IS TOO GREAT FOR BRANCHING NO. WILL APPEAR AT "V" AND "C". USES MONITOR SUB ROUTINES

SUBROUTINE FLOW CHARTS

Following, are flow charts of several subroutines. These are helpful when you write your own programs. The entry requirements necessary to call these subroutines and their exit conditions are also shown.

RESET/MAIN Routine

When the Reset key is released, the CPU outputs FFFE and FFFF to get a starting address. This is the address of the top two locations in the monitor ROM which in turn outputs FC00, the beginning address of the reset routine.

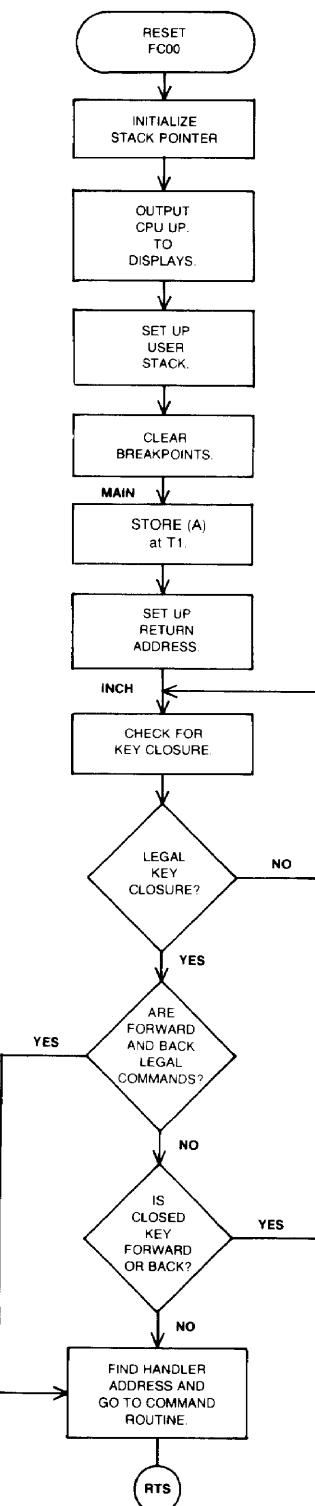

Reset first initializes the stack pointer to 00EB and outputs CPU UP, to the displays. The index register is set to 00CB (the start of the user's stack) and this value is stored in the user's stack pointer at location 00F2.

Breakpoints are cleared by placing FF in the eight RAM locations, 00E4-00EB. The program then goes into the main monitor loop. The contents of accumulator A, which is FF at this point, is stored at T1 and the address to return from command handler subroutines (FC19) is placed on the stack.

The program next calls INCH to scan and encode the keyboard. The program stays in INCH until a key is found closed.

The FORWARD and BACK commands are legal only after execution of the EXAM or SINGLE STEP commands. RAM location 00EE (T1) is cleared if FORWARD and BACK are legal commands. When INCH returns a key closure, T1 is tested to see if FORWARD and BACK are legal. If they are legal, a branch is made to MAIN 2 to obtain the subroutine address to handle the command and then goes to that handler. If FORWARD and BACK are not legal commands, tests are made to see that they are not the key closed before going to MAIN 2. If FORWARD or BACK is found to be the key closed, a branch back to MAIN 1 occurs and INCH is again called to look for a legal key closure.

RESET/MAIN ROUTINE

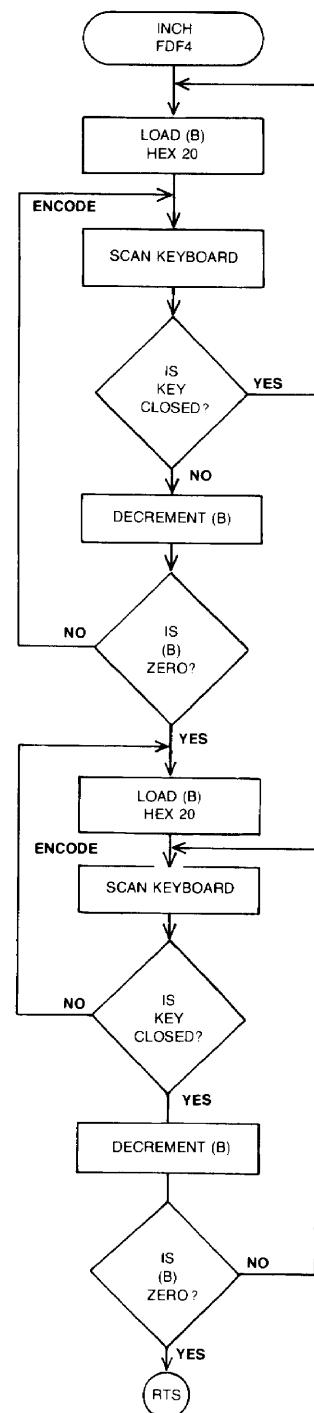

INCH Routine

INCH guards against the entry of a false output from the keyboard due to contact bounce or pressing more than one key. ACCB is loaded with hex 20 and ENCODE is called to scan the keyboard. If C is set (key closed), a branch occurs back to the beginning. If C is clear (no closure), ACCB is decremented and ENCODE is called again. ENCODE must return C clear 32 consecutive times (approx. 9 ms) to exit this loop. The second half of the routine is then entered. This half is identical to that described above, except C must be set 32 consecutive times before exit with the hex value of the key closed in ACCA.

INCH ROUTINE

ENTRY: None.

EXIT: (A) contains hex value of closed key.

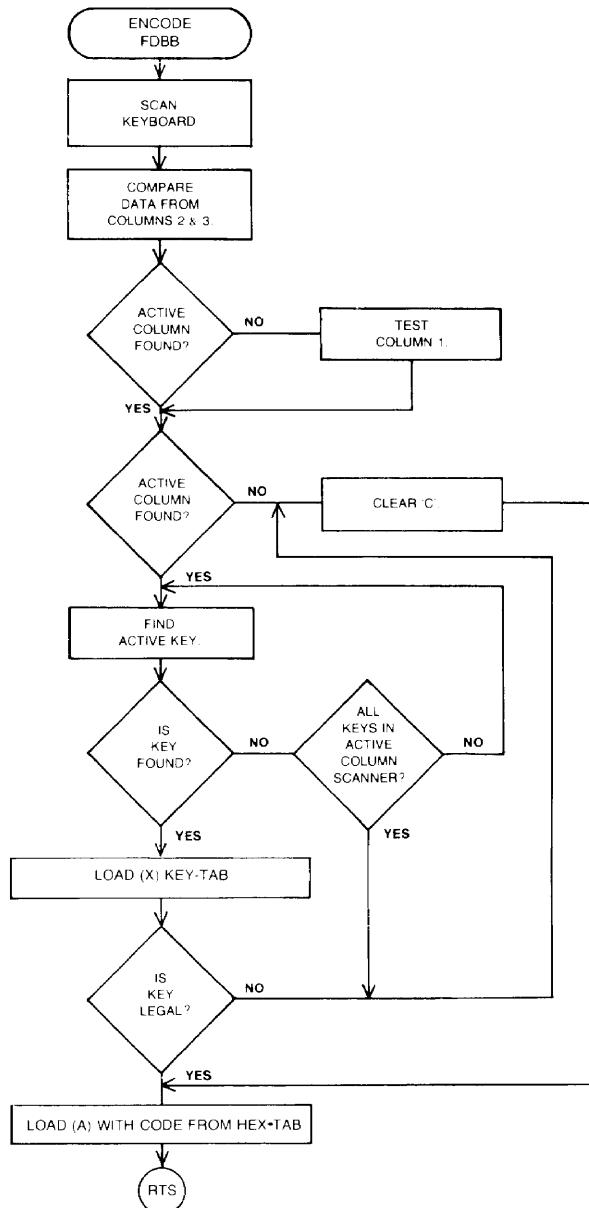

ENCODE Routine

ENCODE is the keyboard scanning routine. If a key is closed, the value is found in the hex table and loaded in ACCA. The C bit in the condition code register is set to indicate a valid key. If no key is closed or if the value is not in HEX-TAB, the C bit is cleared.

ENTRY: None.

EXIT: (A) contains hex value of key closed.
 "C" set for valid condition.

ENCODE ROUTINE

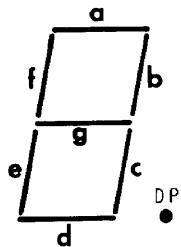

OUTCH Routine

OUTCH outputs a character to the display whose address is contained at memory location DIGADD (00F0-00F1). This routine may be entered at OUTO if the index register does not need to be saved. The code for the character to be displayed must be in accumulator A when the routine is entered. The following drawing shows the segment identification and the corresponding positions in the eight bits of accumulator A. A logic one in a bit will cause that segment to light, whereas a logic zero will keep it off. The hex and corresponding bit codes are shown for two characters used in the monitor program. The most significant bit is DP and the least significant bit is segment g.

Segment codes used by the monitor program are shown at the end of the monitor listing.

	D ₇	D ₆	D ₅	D ₄	D ₃	D ₂	D ₁	D ₀
SEGMENT	DP	a	b	c	d	e	f	g
HEX C 4E	0	1	0	0	1	1	1	0
LTR c OD	0	0	0	0	1	1	0	1

OUTCH ROUTINE

ENTRY: ACCA contains segment code. DIGADD contains address of desired digit. Entry at OUTO if index register is to be saved.

EXIT: DIGADD contains address of next digit to right.

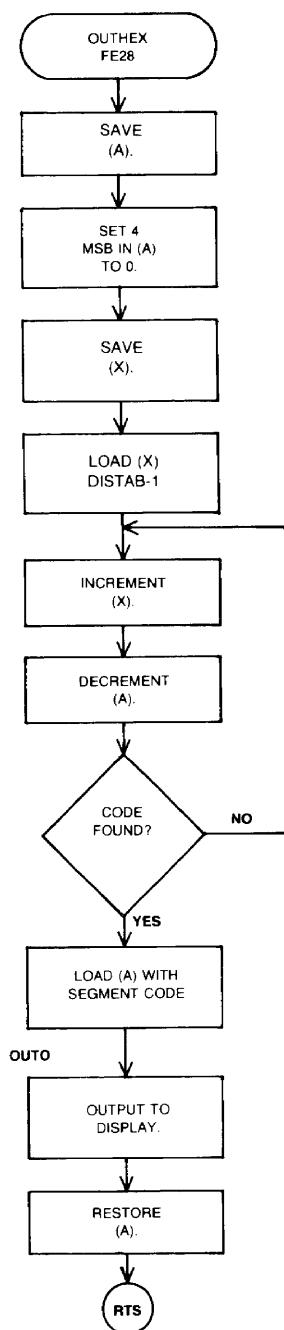

OUTHEX Routine

OUTHEX determines the segment code for a hex value contained in the four least-significant bits (LSB) of accumulator A. Subroutine OUTO is then called to output the hex value to the display whose address is obtained from DIGADD.

OUTHEX ROUTINE

ENTRY: ACCA contains hex value.

EXIT: Address of next digit to right contained in DIGADD.

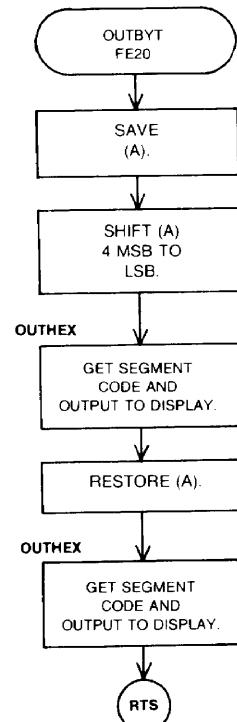

OUTBYT Routine

OUTBYT outputs two hex values contained in accumulator A to two adjacent displays. The value contained in the four most-significant bits (MSB) are moved to the LSB positions. OUTHEX is called to determine the segment code and in turn calls OUTO to output the character to the display addressed at DIGADD. Accumulator A is restored, and OUTHEX and OUTO are called again to output the LSB to the next display to the right.

OUTBYT ROUTINE

ENTRY: ACCA contains two hex values.

EXIT: Digit address for next digit to right contained in DIGADD.

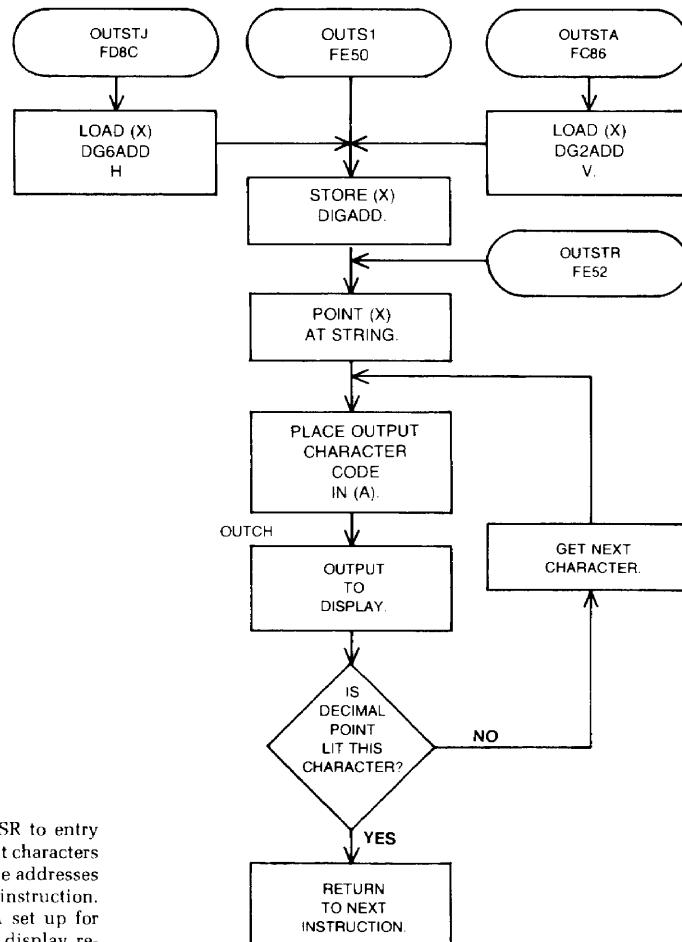

OUTST1 Routine

OUTST1 outputs a string of characters from left to right on the displays. The first character is output to the display whose address is contained in the index register upon entry to the routine. The last character must have the decimal point lit to indicate the end of the string. Adding hex 80 to the desired segment code causes the decimal point to be lit. For example, if the last character is to be LTR P, hex 67 (the last character code) would be hex 67 plus hex 80, or hex E7.

The routine may be entered at OUTSTJ or at OUTSTO (with the first character appearing in the left-most display) or at OUTSTA (with the first character appearing in the V display). Entry at OUTSTR requires the address for the first character to be in DIGADD. Exit from the routine is to the next instruction, which is one plus the address of the last character.

OUTST1 ROUTINE

ENTRY: Calling convention must be JSR to entry point. Segment codes for output characters from left to right at consecutive addresses immediately following jump instruction. Entry at OUTSTJ or OUTSTA set up for left-most character at H or V display respectively. Entry at OUTST1 requires (X) contain left-most digit address. Entry at OUTSTR requires left-most digit address at DIGADD. Decimal point must be lit on last character.

EXIT: To next instruction at 1 + address of last character.
ACCA is clear.
DIGADD contains address of display to right of last digit lit.

DISPLAY Routine

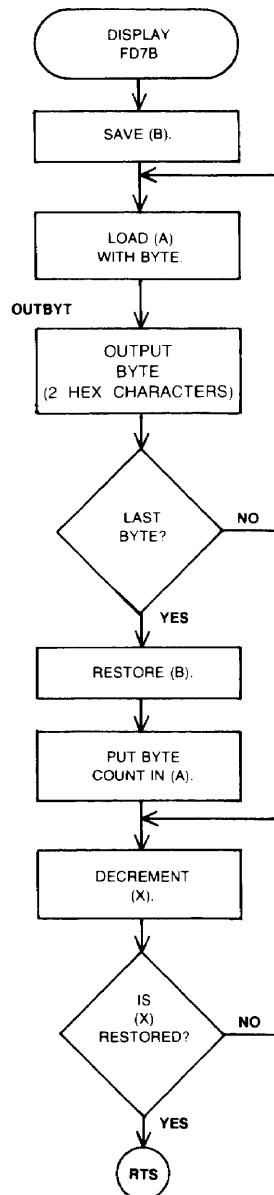

DISPLAY is called to output two or three bytes to the displays. The number of bytes to output is indicated by the contents of accumulator B. This routine could be called to output one byte, although OUTBYT would normally be called for this purpose.

Accumulator A is loaded with a byte value from an address contained in the index register and OUTBYT is called to output the byte to the displays. Then the index register is incremented to get the next byte, accumulator B is decremented, and OUTBYT is called again. When accumulator B is zero, all bytes have been output and the index register and accumulator B are restored before returning from the routine.

DISPLAY ROUTINE

ENTRY: (X) contains address of first byte.
 (B) contains number of byte to output.
 DIGADD contains address of digit.

EXIT: (X) and (B) unchanged.
 Address of next digit to right contained in
 DIGADD.

IHB Routine

IHB outputs two hex characters to the displays corresponding to two consecutive key closures and returns to the calling routine with the byte value of the two closures in accumulator A.

INCH is called to get the value of the first key closure. OUTHEX is called to display the value on the display whose address is contained at DIGADD. The value contained in the four LSB of accumulator A is moved to the four MSB of accumulator A and then saved in accumulator B.

INCH is called again to get the value of the second key closure. OUTHEX is then called again and this value is displayed on the next display to the right.

The contents of accumulators A and B are combined and placed in accumualtor A. Accumulator A now contains the byte value of the two closures. The MSB contains the first closure value and the LSB contains the second value. Accumulator B is restored, accumulator A is pushed onto the stack, and ENCODE is called to wait for the release of the second key. When the key is released, the byte is pulled from the stack and the program returns to the calling routine with the byte contained in accumulator A.

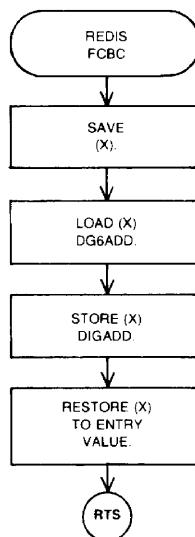

REDIS Routine

REDIS is a short routine to reset the address at DIGADD to the left-most display digit.

REDIS ROUTINE

ENTRY: None.

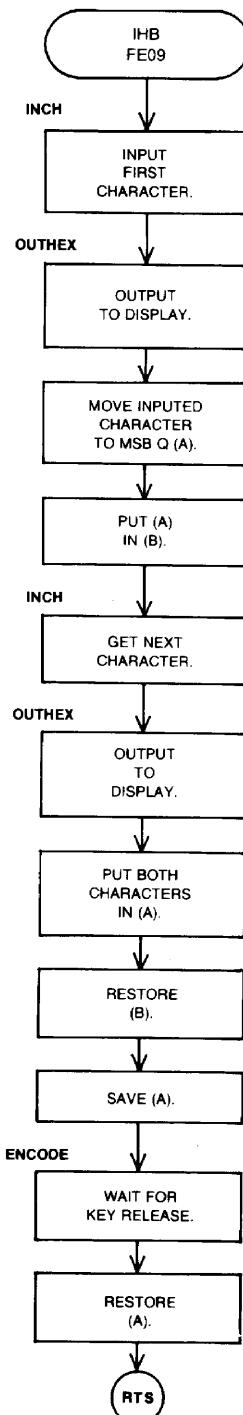

EXIT: DIGADD contains address of left-most digit.

IHB ROUTINE

ENTRY: None.

EXIT: ACCA contains byte value.
Digit address for next digit to right contained in DIGADD.

MONITOR LISTING

Your Trainer is controlled by IC12, the "read only memory" (ROM). The following is a listing of the program stored in this IC.

Tables at the end of the listing show labels used in the program, keyboard and display addresses, segment codes for characters displayed by the program, and addresses in RAM that are reserved for use by the monitor program.

IN CASE OF DIFFICULTY

PICTORIAL 9-1

WARNING: Dangerous AC voltage is present inside the cabinet (where the fuse is located) when the line cord is plugged in. See Pictorial 9-1.

This section of the Manual is divided into three parts: "Visual Checks," "Troubleshooting Chart," and "Detailed Troubleshooting." Use the "Visual Checks" first to find a difficulty that shows up right after your kit is assembled. You can also use the other two sections right after your kit is assembled, or at some future time — if your Trainer ever stops working.

If the trouble is still not located after you complete the "Visual Checks," check voltage readings against those shown in the "Schematic." NOTE: All voltage readings were taken with a high impedance voltmeter (10 MΩ or greater).

In the extreme case where you are unable to resolve a difficulty, refer to the "Customer Service" information inside the rear cover of your Manual. Your Warranty is located inside the front cover.

VISUAL TESTS

1. Recheck the wiring. Trace each lead in colored pencil on the Pictorial as it is checked. It is frequently helpful to have a friend check your work. Someone who is not familiar with the unit may notice something you consistently overlook.
2. About 90 percent of the kits that are returned to the Heath Company for repair do not function properly due to poor connections and soldering. Therefore, you can eliminate many troubles by reheating all connections to make sure they are soldered.
3. Check to be sure that all the integrated circuits are in their proper location and that each IC pin is properly installed in its connector, and not bent or under the IC.
4. Check the values of the parts. Be sure in each step that the proper part has been wired into the circuit, as shown in the Pictorial diagrams. It would be easy, for example, to install a 470 Ω (yellow-violet-brown) resistor where a 4700 Ω resistor (yellow-violet-red) resistor should have been installed.
5. Check for bits of solder, wire ends, or other foreign matter which may be lodged in the wiring.
6. A review of the "Theory of Operation" may also help you determine the trouble.

Precautions

1. Be cautious when you test IC's. Although they have almost unlimited life when used properly, they are much more vulnerable to damage from excessive voltage or current than some other components.
2. Be sure you do not short any terminals to ground when making voltage measurements. If the probe slips, for example, and shorts out a bias or supply point, it is very likely to damage one or more IC or diode.
3. Do not remove an IC while the line cord is plugged in.

Substitution

Corresponding display components can be interchanged; IC's 23 through 28 can be interchanged, for example. If one display unit shows a digit incorrectly, interchange it with one of the other units to determine if the display or the circuit is faulty. If the circuit is faulty and there are no solder bridges on the associated foil, interchange the decoder/driver IC with one of the others. This troubleshooting method can also be used with other problems.

TROUBLESHOOTING CHARTS

NOTES:

1. The following chart lists parts to check. These parts indicate areas of the circuits where problems could exist. Check the circuitry and look for an assembly error or **solder bridge**. Parts are rugged and reliable. Consider a part to be bad last.
2. If you make a repair, make sure you eliminate the cause as well as the effect of the trouble. If,

for example, you find a damaged part, be sure you find out what damaged the part. If the cause is not eliminated, the replacement part may also become damaged when you put the unit back into operation.

3. In several areas of the circuit boards, the foil patterns are quite narrow. When you unsolder a part to check or replace it, avoid excessive heat while you remove the part. A suction-type desoldering tool makes part removal easier.

POWER SUPPLIES

DIFFICULTY	POSSIBLE CAUSE
No +5 V, +12 V, and -12 V supplies. LED1 not lit.	<ol style="list-style-type: none"> 1. Fuse F1. 2. Transformer T1 primary wiring. 3. Line cord wiring.
No +5 V supply, in Standby or On position. LED1 not lit.	<ol style="list-style-type: none"> 1. Transformer T1 secondary wiring (green and green-yellow leads). 2*. Regulator IC31. 3. Short circuit on 5 V line.
No +5 V supply in On position.	<ol style="list-style-type: none"> 1. Switch SW1. 2. Short circuit on main 5 V line.
No +12 V supply in On position.	1.* Regulator IC29.
No -12 V supply in On position.	1.* Regulator IC30.
Have +5 V in Standby position. No +5 V in On position.	1. Shorted main +5 V line.
Have +5 V in Standby position. No +5 V to LED's in On position.	<ol style="list-style-type: none"> 1. Open main +5 V line. 2. Switch SW1.

*The voltage regulator IC's have built-in short circuit protection. Therefore, the lack of voltage at an output connector may indicate a short or open circuit on the circuit board or in the wiring.

Troubleshooting Chart (cont'd.)

7-SEGMENT LED's

DIFFICULTY	POSSIBLE CAUSE
No LED's light when "Segment Test" is shorted.	1. +5 V not supplied to LED's.
All seven segments of one LED do not light when "Segment test" is shorted.	1. +5 V not supplied to this LED.
One segment of an LED does not light when "Segment Test" is shorted.	1. LED segment. 2. Decoder driver. 3. LED not properly installed.
All segments of all LED's lit.	1. Clear line of decoder driver IC's shorted. 2. Jumper wire at terminal blocks A11/A12.
All LED's light dimly when "Segment Test" is shorted.	1. +5 V not supplied to IC's 23 through 28.
All LED's light when "Segment Test" is shorted, but one LED is dim.	1. +5 V not supplied to associated decoder driver IC. 2. Defective decoder driver IC.
All LED's light, except one segment, when "Segment Test" is shorted.	1. Associated LED. 2. Associated decoder driver IC.
One LED stays lit.	1. Associated LED. 2. Associated decoder driver IC.
LED's light dimly when experiments are connected and the Power switch is turned off.	1. This is normal.

DETAILED TROUBLESHOOTING

The microprocessor is very complex, such that any error in the system results in a complete breakdown of the system. Open or shorted address, data, or control lines; their associated IC's; or a non-operating clock will all essentially show the same symptom (that is, when the unit is turned on, some or all of the LED segments will light, but nothing else happens). The following material gives you a systematic check of the Trainer circuitry to help you locate the problem. The material is divided into sections (which are listed below). If you know the section that the trouble is in, proceed to that section and start there. Otherwise, start at "Binary Data LED's."

- Binary Data LED's
- Clock
- Reset
- Address Lines
- Data Lines
- Control Lines
- Decoding

Binary Data LED's

If the +5-volt supply is operating, indicated by the LED1 next to the Power switch being lit, you can troubleshoot your Trainer without using test equipment.

Set the Power switch to On.

Cut a 14" length of yellow wire and remove 3/8" of insulation from each end. Refer to Pictorial 9-2 and insert one end of the wire into the LED connector block labeled 7, or to the block of an LED that you know does not work. Insert the other wire end into the +5 connector block. The LED directly above the connector block should light.

If the LED does not light:

- A. Visually inspect the LED's. The flat at the base of each LED should face the top of the circuit board.

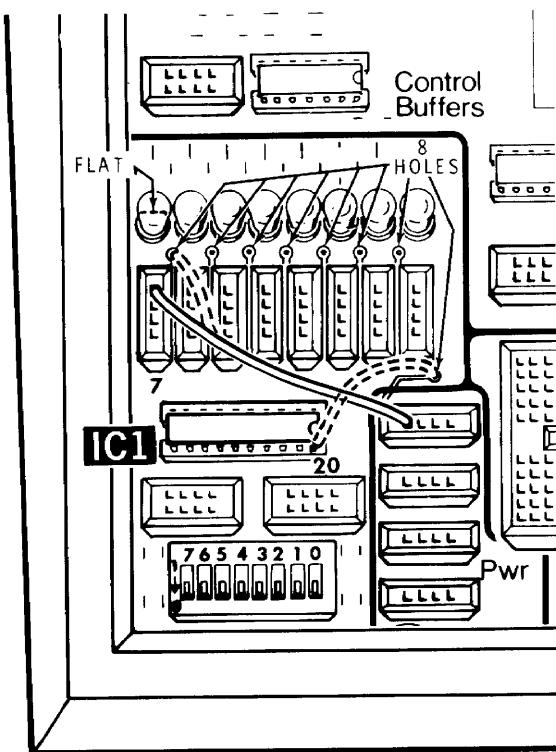

- B. Unplug the line cord, remove IC1 from its socket, and plug the line cord back in.

With the indicated end of the yellow wire, one at a time, touch the eight circuit board plated-through holes shown. The eight LED's should light one at a time. If they do not, replace the LED that does not light.

- C. With pliers, flatten one end of the yellow wire.

Carefully insert the wire into pin 20 of socket IC1 and touch the other wire end to the indicated plated-through hole. The 0 LED should light. IF it does not light, check the IC socket pins and the circuit board foils to find out why +5 volts is not at pin 20 of the socket. Then remove the yellow wire.

- D. Unplug the line cord.

PICTORIAL 9-2

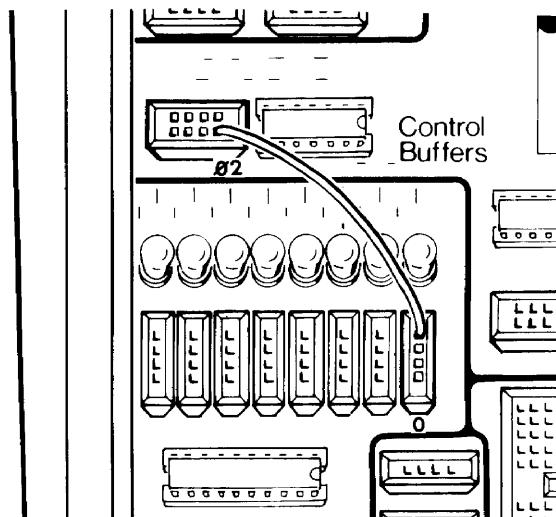

Be sure the pins of IC1 are straight and then properly reinstall the IC in its socket.

Reconnect the yellow wire to LED connector block 7 (or to the connector block of an LED that you know was not working) and the +5 connector block. The data LED should light. If it does not light, replace IC1.

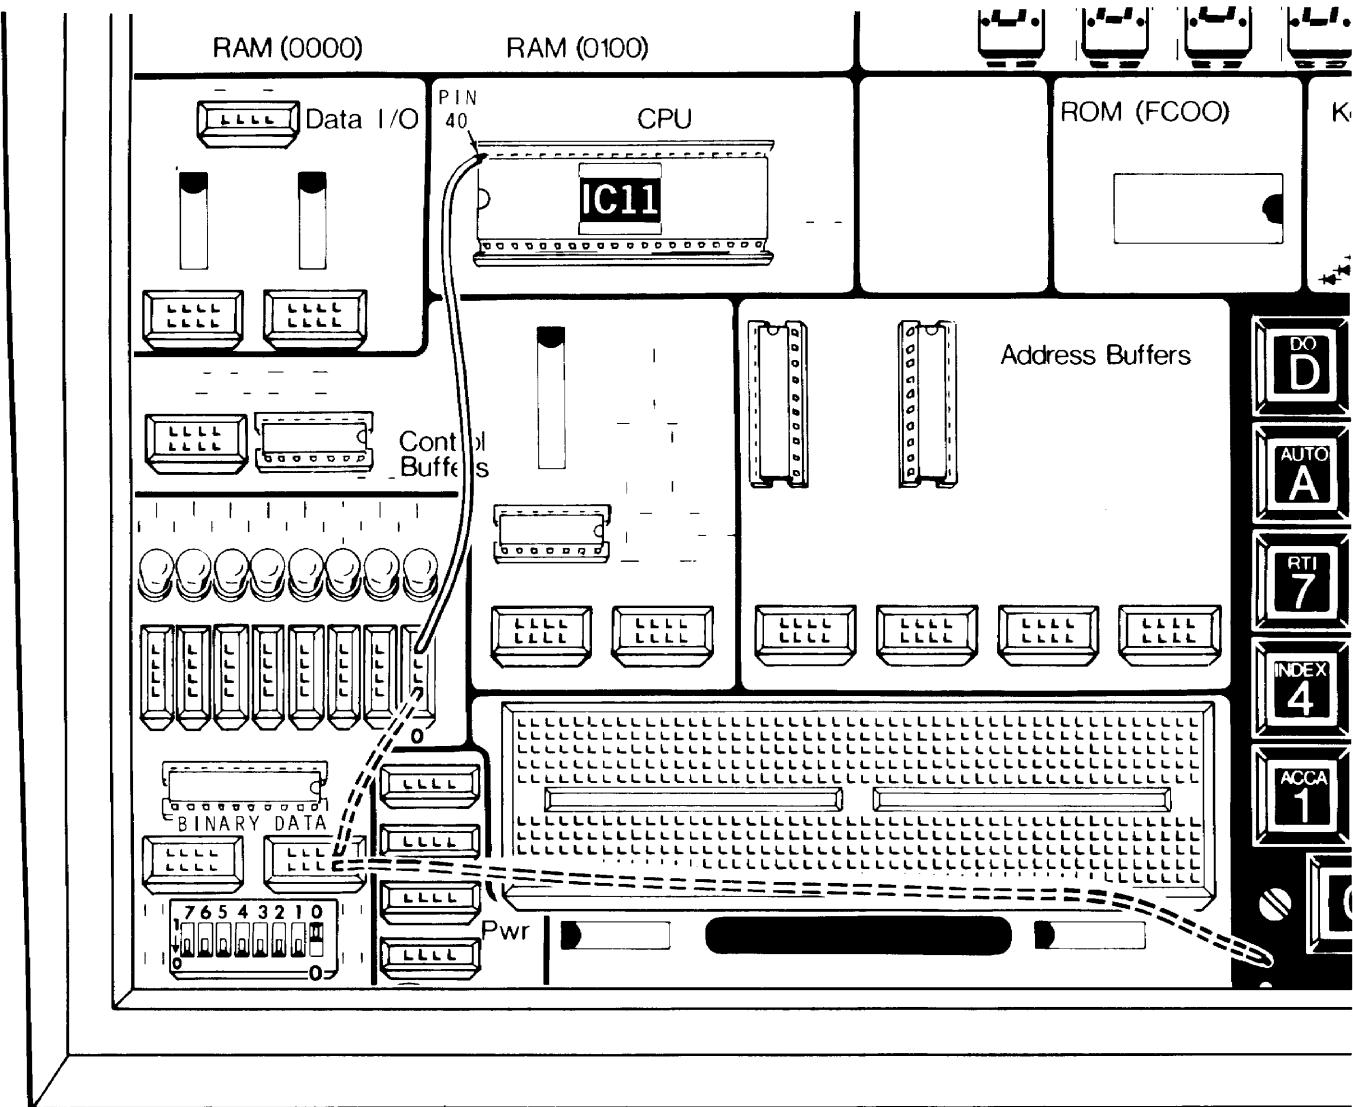

Clock

The simplest test to determine if the clock (IC19) is operating is to place a portable radio near the clock and tune the radio across the broadcast band. If the clock is operating, you will hear several "beat" signals. Unplug the Trainer's line cord and the beat signal will disappear if it is caused by the microprocessor clock.

There are four different clock outputs used in the system (pins 7, 9, 13, and 15). Usually, the outputs of a clock that has failed will assume a logic 0 state. To test the clock, use a wire and connect a data LED (LED 2 through LED 9) to the clock's four outputs. If the clock is working, the LED will light but it will be noticeably dimmer than the same LED connected to +5 volts. This is due to the 50% duty cycle of the clock. See Pictorial 9-3.

PICTORIAL 9-3

PICTORIAL 9-4

Reset

Refer to Pictorial 9-4 and connect a wire from a data LED connector block to IC11 pin 40. The LED should light. While you hold the test lead on pin 40, press the Reset key. The LED should go out while the Reset key is pressed and come back on again when it is released. Then remove the wire.

To test the reset input, connect a wire from the indicated Binary Data connector block to LED connector block 0.

Set data switch 0 to logic 1.

Connect another wire from the indicated Binary Data connector block to the circuit board soldered connection just left of the 0 key. The lamp should stay on until you push the Reset key; then it will go out. It will come back on when you release the key.

Other effects of pushing the Reset key will be covered later after you check the address and data lines. Remove the two wires.

Test Wires

The following paragraphs instruct you how to make indicators for testing tri-state* devices. These are necessary for testing address and data lines in the following sections.

Unplug the line cord.

Refer to Pictorial 9-5 (Illustration Booklet, Page 9) and unsolder and disconnect the indicated lead of resistor R24 from the circuit board as shown.

Prepare a 2" yellow wire. Temporarily solder one end of the wire to the free lead of the resistor and plug the other end of the wire into connector block 6.

Prepare two 12" yellow wires. Remove 3/8" of insulation from both ends of each wire.

Insert one end of one wire into LED connector block 7.

Insert one end of the other wire into LED connector block 6.

In the following sections, these two wires will be referred to as test wire 7 and test wire 6. Be sure you reconnect and resolder the loose resistor lead after you locate and repair the problem.

Plug in the line cord. LED 7 should be on and the other data LED's should be off.

Address Lines

In checking the buffered address lines, you will look for two basic problems:

1. Lines that are shorted.
2. Lines that are not connected properly.

To perform these tests, you will tri-state the CPU. In this state, the address lines from the CPU and from the buffers are in a high impedance state. Therefore, any logic level can be put on these lines. Data input switches will apply test logic levels to the address lines, and data LED displays will serve as logic level indicators.

Prepare the following yellow wires. Cut them to the lengths shown and remove 3/8" of insulation from each end:

<u>WIRES</u>	<u>LENGTH</u>
3	4"
2	8"

Refer to Pictorial 9-5 and connect a 4" wire from the ground connector block to TSC.

Touch test wire 6 to the +5 connector block to test the LED. LED 6 should light. Touch test wire 6 to IC11 pin 39. LED 6 should again light; this indicates proper TSC voltage. If the LED does not light, proceed to "Control Lines" tests on Page 103.

Touch test wire 6 to IC7 pin 1 and then to IC8 pin 1. The LED should light both times. This indicates proper tri-state voltage. If the LED does not light, proceed to "Control Lines" tests on Page 103.

Touch test wire 7 to IC7 pin 19 and then to IC8 pin 19. LED 7 should go out both times; this indicates the correct voltage to tri-state the address buffers.

One after another, touch test wire 7 to each address output connector (A_0 - A_{15}). LED 7 will remain lit unless the line touched is shorted to logic 0. If the LED goes out, trace the foil pattern and look for a solder bridge. If this does not solve the problem, then remove the IC's connected to that line, one at a time, to check for a defective IC. CAUTION: Do not remove or install IC's with the line cord plugged in. If you remove a MOS IC, place it in the protective foam in which you received it. This will prevent possible damage from a static charge. (See Page 36 for instructions on how to handle MOS IC's.)

One after another, touch test wire 6 to each address output connector. The LED will remain unlit. If the LED should light, it indicates a short to logic 1. Use the same procedure as above to check for the cause of the problem.

* Registered Trademark, National Semiconductor

The next test is to make sure that none of the address lines are shorted together. To do this, you will put a logic 1 on one line and a logic 0 on the line beside it. If the two lines are shorted together, the logic 0 will cause both LED's to be off. You will also check to see that the address line is indeed connected to all the IC's where it should be.

Connect a 4" wire from the connector block of data switch 0 to the connector of data LED 0.

Connect a 4" wire from data switch 1 to LED 1.

Place the data 0 switch to logic 1 and the data 1 switch to logic 0.

Connect an 8" wire from data LED 0 to A₀, and an 8" wire from data LED 1 to A₁. LED 0 should be on and LED 1 should be out. If there is a short between lines A₀ and A₁, both LED's will be out. If the LED's are out, check for solder bridges or defective IC's.

Connect test wire 6 to all the IC pins indicated in the following chart as being connected to A₀ (IC7 pin 12,

IC12 pin 24, etc.). The LED should light as each pin is touched. If it does not light, an open circuit exists between the address terminal and the pin being tested.

Move the wire that is at line A₁ to A₂. Then move the wire at A₀ to A₁.

As before, LED 0 should be on and LED 1 should be out. If both LED's are out, this time check for a short between lines A₁ and A₂.

Connect test wire 6 to all the IC pins indicated in Test Chart A as being connected to A₁. The LED should light as each pin is touched.

Continue moving the two wires towards A₁₅, one position at a time, and make the tests in the above three steps until all the address lines have been checked.

TEST CHART A

BUFFERED ADDRESS LINES	BUFFERS		ROM IC12	RAM IC14 IC15 IC16 IC17	DISPLAY LATCHES IC23 IC24 IC25	ADDRESS DECODING			
						IC26	IC27	IC28	IC2
	IC7 PIN	IC8 PIN				PIN	PIN	PIN	IC3
A ₀	12		24	4		1			
A ₁	14		23	3		2			
A ₂	16		22	2		3			
A ₃	18		21	1					
A ₄	9		20	15					15
A ₅	7		19	5					14
A ₆	5		18	6					13
A ₇	3		17	7					
A ₈		12	16						15
A ₉		14	15						14
A ₁₀		16	14						15
A ₁₁		18	13						14
A ₁₂		3	10						12
A ₁₃		5					15		
A ₁₄		7					14		
A ₁₅		9					13		

To check the address lines between the CPU and the address connectors, it is necessary to remove the tri-state condition from the buffers and the CPU.

Be sure the line cord is unplugged.

Remove IC11 from its socket.

Remove IC5 and bend pin 11 out slightly. Then reinstall the IC so that pin 11 is not in the socket.

Remove all the previously installed wires except test wires 6 and 7.

Follow chart below and reconnect the wires.

WIRE	FROM	TO
4"	Data switch 0	LED 0
4"	Data switch 1	LED 1
4"	+5	BA
8"	LED 0	A ₀
8"	LED 1	A ₁

Set data input switches 0 and 1 to logic 1.

Plug in the line cord.

Use test wire 6 and check for correct logic levels at IC7 and IC8. Pin 1 is logic 0 (LED 6 off) and pin 19 is logic 1 (LED 6 on).

Address lines A₀ and A₁ should be logic 1, indicated by LED 0 and LED 1 being lit. Remove the 12" test wire from LED 7 and insert one end in the GND connector.

Touch the free wire end to IC7 pin 8. The LED connected to A₀ should go out, while the LED connected to A₁ will remain lit. If both LED's go out, there is a short circuit between the A₀ and A₁ lines, between the CPU and the buffer inputs.

Follow Test Chart B to check all the address lines.

TEST CHART B

8" WIRE FROM LED 0 TO:	8" WIRE FROM LED 1 TO:	GND		TURNS OFF LED
		IC	PIN	
A ₀	A ₁	7	8	0
A ₂	A ₁	7	6	1
A ₂	A ₃	7	4	0
A ₄	A ₃	7	2	1
A ₄	A ₅	7	11	0
A ₆	A ₅	7	13	1
A ₆	A ₇	7	15	0
A ₈	A ₇	7	17	1
A ₈	A ₉	8	8	0
A ₁₀	A ₉	8	6	1
A ₁₀	A ₁₁	8	4	0
A ₁₂	A ₁₁	8	2	1
A ₁₂	A ₁₃	8	17	0
A ₁₄	A ₁₃	8	15	1
A ₁₄	A ₁₅	8	13	0
A ₁₄	A ₁₅	8	11	1

Properly replace IC11 and IC5 into their sockets.

Remove all the wires except the test wires.

Data Lines

To check data lines for opens and shorts, you will input data through the data buffers, alternate logic 0 and logic 1 on adjacent data lines, and then look for the correct data at the affected IC pins. To do this, you will need the following yellow wires. Cut them to the lengths specified and remove 3/8" of insulation from each end.

<u>WIRES</u>	<u>LENGTH</u>
3	8"
3	4"

If not already done, refer to Page 97 and prepare the two test wires as instructed there.

Refer to Pictorial 9-6 (Illustration Booklet, Page 9) and install a 4" wire between GND and TSC to tri-state the CPU.

The data I/O buffers are bi-directional transceivers with the enable line to provide data to the output connectors.

Touch test wire 6 to pins 1 and 13 of IC9 and IC10. The LED should light, indicating that the buffers are in the right state.

Touch the test lead to each of the data connectors (D_0-D_7). The lamp should light at each terminal, indicating that the data lines are tri-stated and none of the data lines are shorted to ground. If the LED does not light, check both the terminal and the CPU sides of the data lines involved.

Install the following jumper wires.

<u>WIRE</u>	<u>FROM</u>	<u>TO</u>
4"	Data switch 0	LED 0
4"	Data switch 1	LED 1
8"	LED 0	D_0
8"	LED 1	D_1
8"	GND	\overline{RE}

Set data switch 0 to logic 1.

Set data switch 1 to logic 0.

Refer to Test Chart C and touch test wire 6 to any IC pin to which line D_0 is connected. The LED should light. If the LED does not light, there is a short between the D_0 and D_1 lines. Visually check for shorts. Remove the IC's connected to the D_0 and D_1 lines, one at a time, to determine if a short exists in an IC. CAUTION: Do not remove or install IC's with the line cord plugged in. If a short is not indicated, test all pins to which line D_0 is connected by moving the data switch from logic 1 to logic 0 while you touch each pin with the test wire. If you do not obtain the correct results at all pins, check for an open circuit to the pin not showing the proper response. (NOTE: Line D_0 also goes to the display latches and is inserted at IC21 pins 9 and 10.)

Move the leads from LED 0 and LED 1 to buffer data connectors D_1 and D_2 , and repeat the test for D_1 . Continue this procedure until you have checked all the data lines.

TEST CHART C

BUFFERS				CPU	ROM	RAM		KEYBOARD BUFFER
CONNECTOR SIDE		CPU SIDE				IC15 & IC17 PIN	IC14 & IC16 PIN	
	IC9 PIN	IC10 PIN	IC9 PIN	IC10 PIN	IC11 PIN	IC12 PIN		IC13 PIN
D ₀		8		6	33	2	9	3
D ₁		9		5	32	3	10	5
D ₂		10		4	31	4	11	9
D ₃		11		3	30	5	12	7
D ₄	8		6		29	6		9
D ₅	9		5		28	7		10
D ₆	10		4		27	8		11
D ₇	11		3		26	9		12

Line D₀ is also applied to IC21 pins 9 and 10. The D₀ output, IC21 pin 8 and IC6 pin 2, is connected from the output of IC6 (pin 18) to pin 13 of IC23 through IC28.

Remove all the wires except the test wires.

Control Lines

If not already done, refer to Page 97 and prepare the two test wires as instructed there.

There are nine lines other than data, clock, and address that affect the operation of the CPU. Four lines are always logic 1, unless they are pulled low by an external connection. These are RESET, HALT, IRQ,

and NMI. Reset has been checked earlier in this section and will be covered again later in greater detail. The three other lines are connected through noninverting buffers to the CPU. The connector and the associated CPU pin are therefore at the same logic level. To test these three lines, touch test wire 6 to the connector and then to the corresponding CPU pin. The LED should light at both locations. Then repeat this procedure with a wire installed from GND to the connector block associated with the line being checked. The LED should not light at either the connector or the CPU pin.

In the above test, if you fail to get the correct indication, check for open or shorted lines. Also, IC6 may be defective.

To check the five remaining control lines ($\overline{R/W}$, TSC, BA, VMA, and DBE) plus $\overline{VMA\phi 2}$, you will use Halt and TSC, which forces a given logic level to appear on these control lines. Refer to the following chart and connect a wire from ground to the designated connector, and check for the desired result by touching test wire 6 to the indicated connector or IC pin.

TOUCH GROUND WIRE TO CONNECTOR	DBE IC11 PIN 36	TSC IC11 PIN 39	$\overline{R/W}$ IC11 PIN 34	VMA IC11 PIN 5	BA IC11 PIN 7	IC4 PINS 1, 4, 10	IC4 PIN 13	$\overline{VMA\phi 2}$	BA	TSC	$\overline{R/W}$
—	1	0	1	1	0	1	1	1 ¹	1	1	1 ²
HALT	0	0	0	0	1	0	0	1	0	1	1
\overline{TSC}	0	1	0	0	0	0	1	1	1	0	1

¹ The $\overline{VMA\phi 2}$ state does not appear to change. However, the LED will not be as brightly lit when the CPU is running as it is when the CPU is in the Halt or TSC states.

² Although the $\overline{R/W}$ line changes, the output connector does not change because the buffer is tri-stated when $\overline{R/W}$ is low.

RESET

Previous tests indicated that the logic level on this pin is correct.

When the Reset key is closed, reset goes low, VMA and BA are low, and $\overline{R/W}$ is high. In addition, the CPU puts the first address of the reset sequence on the address line. This address is FFFE. Therefore, test all the address lines with test wire 6. They will all be logic 1 except for A_0 , which is logic 0.

Decoding

In this section, you will put various addresses on the lines and then refer to the "Decoding Chart" and look at logic levels at the decoding IC's to check their operation. In each case, $\overline{VMA\phi 2}$ must be logic 0 in order to provide the proper addressing.

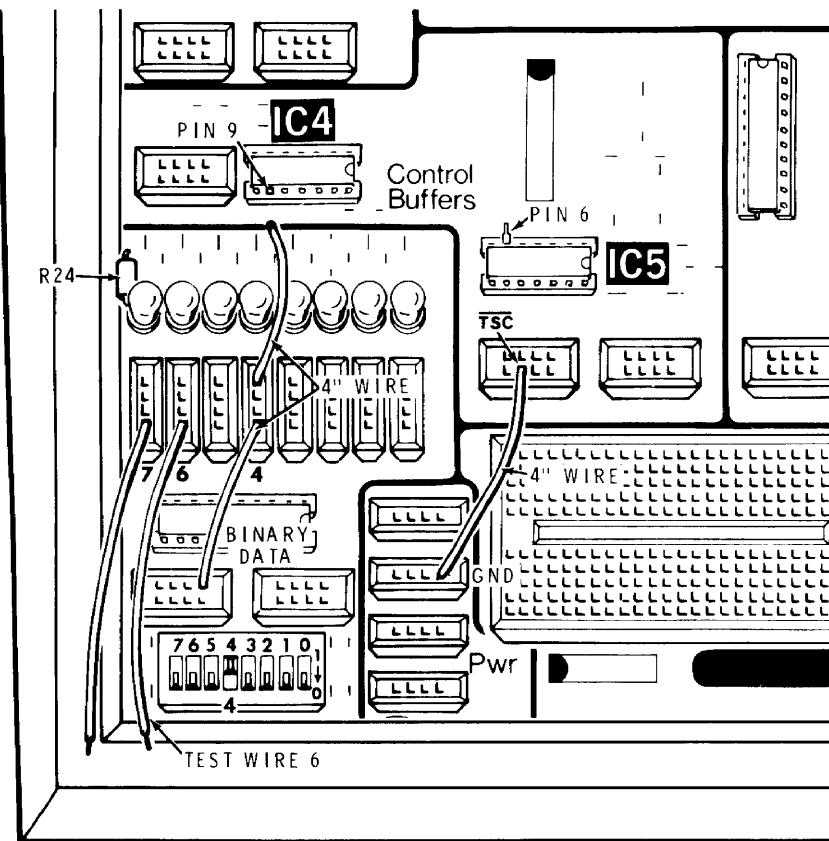

If not already done, refer to Page 97 and prepare the two test wires as instructed there.

$\overline{VMA\phi 2}$, for internal operation, is taken from the line connecting IC5 pin 6 to IC4 pin 9. To perform tests on the decoding section, you will need to pull this line to logic 0. To avoid damaging IC5 when you do this, refer to Pictorial 9-7, carefully remove IC5 from its socket, bend pin 6 out just far enough to clear the edge of the socket, and then reinstall the IC so that pin 6 is not in the socket.

Install one end of a 4" wire in LED 4. Insert the free end of this wire in the plated-through hole just below pin 9 of IC4. Temporarily solder this point on the bottom side of the circuit board.

Install a 4" wire from LED 4 to data switch 4. Data switch 4 will now determine the logic level of $\overline{VMA\phi 2}$, and LED4 will display the level. 1 is ON, 0 is OFF.

Install a 4" wire from GND to \overline{TSC} to tri-state the address lines so you can place an address on the lines.

PICTORIAL 9-7

In the following steps, refer to Pages 10 and 11 in the Illustration Booklet and use test wire 6 to check for proper address decoding. It is not necessary to go through the entire "Decoding Chart" unless the "End Result" is not correct. After you place an address on the address lines, check all the end results to make sure a problem does not exist, which results in more than the desired function being addressed. The logic level on the pins listed in the End Result column should be opposite of that indicated when the IC or function is not being addressed.

To address RAM 00 — Install a wire from A_{15} to GND. Then install wires from A_{15} to A_{14} , A_{14} to A_{13} etc., until lines A_8 through A_{15} are all connected together. To make sure $VMA\phi 2$ is doing its job, switch D4 between logic 1 and logic 0. The chart "End Result" should only be obtained when $VMA\phi 2$ is logic 0.

To address RAM 01 — Remove the wire installed between A_8 and A_9 for RAM 00 — Install a wire from A_8 to +5.

To address ROM FC — Remove the wire installed between A_9 and A_{10} , and install it between A_8 and A_9 . Move the wire from A_{15} to +5, and the wire from A_8 to GND instead of +5.

To address the keyboard C0-X — Remove the wire from between A_{14} and A_{13} , and install it between A_9 and A_{10} . Address lines A_3 through A_7 are "don't care" lines, so let them float. Install 4" wires from data switch 0, 1, and 2 to the corresponding LED terminals and 8" wires from the connectors to the corresponding address lines.

With the keyboard address on the lines, first look for the proper end result in the "Main Decoding Chart." If it is correct, proceed to the "Keyboard Column Address Decoding Chart."

In order to determine if a key is depressed, the monitor program causes the CPU to put the keyboard address on the line. Then it looks at the data lines to determine if a key is closed, which is indicated by the presence of a logic 0 on one of the affected data lines (D_0 through D_5). The eight high-order bits (C0 hex) are decoded and enable the keyboard buffer.

The three lower-order bits (3, 5, or 6 hex) place a logic 0 on one of the key columns. If a key is closed in the column address with a logic 0, a logic 0 will appear on the corresponding data line. Then you can tell which key is closed.

Place data switches 0, 1, and 2 in their logic 1 positions. The address lines to the key columns are all logic 1 and no key is actually addressed. Depress keys F, E, and D. All data lines should remain logic 1. If a line is logic 0, it indicates a shorted address line to the column of keys containing the depressed key.

Put the address for the right-hand column of keys (hex 3) on the three low bit address lines using the data switches. The LED will indicate that the address is correct. Connect the logic probe to each of the data output connectors, D_0 through D_5 . All the connections should be logic 1. If one of the data lines should be logic 0, a short to GND is indicated in the keyboard circuit. This could be caused by the key associated with the data line or it could be the row of three keys. For example, with the hex 3 address on the line, we find D_0 to be logic 0. The problem could be a short that only affects key F, or it could be a short affecting the row of keys D, E, and F. If you change the hex 3 portion of the address to either hex 5 or hex 6, and D_0 changes to logic 1, the short is only associated with key F. However, if the logic 0 remains, the problem is associated with the line to the entire row.

If the data lines are all logic 1 with no key depressed and a hex 3 address, depress Key F. Look at all the data lines while the key is depressed. Only D_0 should be logic 0. If, for example, lines D_0 and D_1 indicate logic 0, a short exists between keys F and C, or between the rows of keys D, E, F, and A, B, C. Again, to determine individual key versus rows of keys, change the column address to hex 5 and depress key E. If only D_0 is now logic 0, the problem exists between keys F and C. If D_0 and D_1 are logic 0, the problem is a short between the D, E, F and A, B, C rows or keys.

With the hex 3 address on the line, depress keys D and E. If data line D_0 goes to logic 0, a short is indicated between the column of key associated with the key depressed and the column containing the F key.

To address the display LED's CIX —. Remove the wire at A_8 - A_9 . Move the GND wire from A_8 to A_9 . Then connect a wire from A_8 to +5. Check for the proper end result indicated in the Main Decoding Chart. Move the 8" wires installed at A_0 , A_1 , and A_2 to A_4 , A_5 , and A_6 . Use data switches 0, 1, and 2 to apply the LED address as shown in the Display LED Chart. Test for the proper logic level at pin 14 of the addressed IC.

To address an LED segment CIXX, move the 8" wires from A_4 , A_5 , and A_6 to A_0 , A_1 , and A_2 respectively. Now use data switch 0, 1, and 2 to address the desired segment. Move the wire soldered to $\overline{VMA\phi 2}$ from LED4 to GND. Install 4" wires from data switches 3, 4, and 5 to LED connectors 3, 4, and 5. Install 8" wires from LED 3, 4, and 5 to address lines A_4 , A_5 , and A_6 . (NOTE: The data switches are one number from the corresponding address line so LED's 6 and 7 can still be used as logic level indicators.) Data switches 3, 4, and 5 can now be used to address the desired display LED.

The D_0 data line controls the state of the LED segment when the segment is addressed and $\overline{VMA\phi 2}$ is logic 0. If D_0 is logic 1, the segment will light and if D_0 is logic 0, the segment will be off. The D_0 data line is connected through IC21 and IC6 to the D data input (pin 13) of decoder latch IC's.

The "D₀ Logic Level Chart" shows the levels at the various connections on the D₀ segment control line. To control the logic level on the D₀ data line, connect an 8" wire from \overline{RE} to GND. Connect another 8" wire to the D₀ connector. The free end of this wire need not be connected to provide a logic 1, but it must be connected to GND to provide a logic 0 level on D₀. To test this area, place the address for an LED and a segment on the low-order address lines, touch the output pin that should be affected with test wire 6, and then watch both the probe and the selected LED segment. If D₀ is logic 1, the segment should light and the logic probe should indicate logic 0. The reverse is true if D₀ is logic 0.

If you wish to check different LED's or segments, insert the D₀ input lead into the 1 Hz square wave connector. The address segment will turn on or off approximately every 1/2 second.

To test the latch action of the decoder latches, move the lead soldered to $\overline{VMA\phi 2}$ from GND to LED 6 and add a wire from LED connector 6 to data switch 6. If data switch 6 is logic 0, the addressed LED segment will follow the D₀ logic level. To check the latching action, move data switch 6 from 0 to 1 while the addressed LED segment is either on or off. The segment should remain in the state it is in when $\overline{VMA\phi 2}$ is moved to logic 1.

Remove the wires from your Trainer, properly replace IC5, and then reconnect and resolder the free lead of resistor R24.

SPECIFICATIONS

CPU (Central Processing Unit)	8-bit parallel, NMOS, bus oriented 6800.
ROM (Read Only Memory)	NMOS, 1024 bytes.
RAM (Random Access Memory)	NMOS, 256 bytes (plus sockets for additional 256 bytes).
Clock Frequency	500 kHz (approximately).
Display	Six 7-segment LED digits.
Keyboard	Hexadecimal (0-F and Reset). 1 through F are dual-function keys and also enter commands.
Input Switches	Eight miniature switches in a dual-in-line package. (For experiments.)
LED Monitor Lights	Eight red LED's with separate input terminals. (For experiments.) +5 volts at 1.5 amperes (.5A available for breadboard at output terminal.)
Power Supplies	+12 volts, and -12 volts at 50 milliamperes at output terminals.
Power Requirements	105-130 volts or 210-260 volts rms, 50-60 Hz, 30 watts maximum.
Fuse	3/8-ampere, slow-blow.
Dimensions	12-1/8" wide × 11-3/4" deep × 3-1/2" high. (30.8 × 29.8 × 8.9 cm.)
Net Weight	4 lbs (1.8 kg).

The Heath Company reserves the right to discontinue products and to change specifications at any time without incurring any obligation to incorporate new features in products previously sold.

THEORY OF OPERATION

As you read this section, refer to the Block Diagram (Illustration Booklet, Page 12) and the Schematic (fold-in).

The operation of the CPU (microprocessor, IC11) is very complex. Therefore, this section of the Manual will not discuss the internal operation of the CPU, but will discuss how the sections of circuitry in your Trainer operate together. For information concerning the CPU, refer to Motorola's M6800 application manual.

Many lines are connected to front panel connectors, as shown on the Schematic. Some are buffered and some are not. Most of these connections and their buffers will not be mentioned in the following paragraphs.

The Reset key is connected to the clock (IC19) which produces a proper reset pulse. This pulse is applied through tri-state buffer IC6 to the reset input (pin 40) of the CPU.

Two non-overlapping outputs are connected from the clock to the CPU. The memory ϕ_2 output is used for internal timing and is connected through IC4 to the DBE input (pin 36) of the CPU.

The VMA line from the CPU is buffered by IC6 and then NANDed by IC5B with memory ϕ_2 to produce $\overline{\text{VMA}\phi_2}$. This signal is then applied to the address decoding circuits.

The CPU R/W line is coupled through IC4 to the R/W inputs of RAM.

The input signal to TSC is applied through inverter IC5C. TSC is normally logic 0 and is connected through IC4 to the input of IC5A and to \overline{G} of the address buffers, IC7 and IC8. Line BA is normally connected through IC5D to the control line of the TSC portion of IC4. The output of IC5A is logic 1 and is connected to the control lines in IC4 for R/W, DBE, and $\overline{\text{VMA}\phi_2}$; keeping these sections enabled. The output of IC5A is also connected to an enable input of the address buffers.

If TSC is pulled to logic 1, the input to IC5A and \overline{G} on the address buffers also become logic 1. The output of IC5A and, therefore, the inputs to address enable and

the control lines for the other three sections of IC4 become logic 0. The address, R/W, DBE, and $\overline{\text{VMA}\phi_2}$ buffers are all tri-stated. In this state, DBE is held at logic 0 by a pull-down resistor and the other three lines are held at logic 1 by pull-up resistors. When BA goes to logic 0, the TSC section of IC4 is tri-stated, TSC does not control the output, and the output is held at logic 1 by a pull-up resistor which tri-states the address buffers R/W, DBE, and $\overline{\text{VMA}\phi_2}$ as described above.

The address lines are buffered by IC7 and IC8. The buffers have active outputs or are tri-stated as previously described.

The eight high-order address lines are connected to the address decoding IC's; $\overline{\text{VMA}\phi_2}$ is also applied to the decoding section. This line must be logic 0 to obtain proper decoding. With the high-order byte 00 on the lines, a logic 0 is placed on CE for IC14 and IC15, and its 256 bytes of RAM memory may be addressed by lines A_0-A_7 , R/W from the CPU determines if information is to be stored into or read from the RAM.

High-order byte 01 does the same thing for the optional 256 bytes of RAM at that address.

With the high-order byte FC, FD, FE, FF; the address decoder places a logic 0 in \overline{CS}_1 of the ROM. Address lines A_{10} , A_{11} , and A_{12} place logic 1 on CS0, CS2, and CS3; and lines A_0 through A_9 can address the 1024 bytes of read only memory.

Buffer IC13 is normally in its tri-state condition. When the high-order address byte C0 is decoded, a logic 0 is placed on its control lines to enable it. Address lines A_0 , A_1 , and A_2 apply a logic 0 to one of the key columns and logic 1 to the other two columns. If a key is closed in the column with Logic 0 on it, a logic 0 is placed on the data line for the row of keys. Which key is closed is determined by the monitor program by knowing the address that is on the line and which data line is 0. The diodes in series with the three address lines serve as buffers to prevent two adjacent keys from accidentally changing the address due to the lines being shorted together.

When high-order address byte C1 is decoded, the output of the decoder places a logic 0 on the D input of IC22. IC22 is a 4 to 10 line decoder. If a BCD number from 0 through 10 is placed on the inputs, the output line corresponding to that number will be logic 0. Output lines 1 through 6 are connected to the enable inputs of the six display latch drivers, IC23 through IC28. If the D input to IC22 (which is BCD equivalent of 8) is high, the BCD input will always be greater than 8 and the output lines actually in use cannot be decoded. With the D input held low, the BCD information supplied to the other three inputs will be 0 through 7. These three inputs are connected to address lines A₄, A₅, and A₆ and will determine which output line will be logic 0 by their logic levels. A hex 6 or BCD 110 on lines A₆, A₅, and A₄ will cause the enable line for the left-most latch driver (IC23 and DISPLAY LED H) to be logic 0. Hex 1 or BCD 001 enables IC28 and DISPLAY LED C.

Address lines A₀, A₁, and A₂ are connected to the latch select inputs of all six latch drivers. The BCD code on these lines (hex 0 through 7), is decoded in the enabled IC and results in the corresponding output line following the logic level on the D input of that IC. Each of the output lines is connected through one of seven segments of display LED or decimal point, and a current-limiting resistor, to +5 V. If the D input is logic 0 the addressed output line will be 0 also, and a corresponding segment will be lit. If D is logic 1, the output line is 1 and the segment will be out. The D₀ data line is inverted by IC21C and applied to the latch driver D inputs through IC6. Therefore, if line D0 is logic 1, the D input is logic 0 and the addressed segment will be lit. If D0 is logic 0, the addressed segment is off. The status of the output lines and LED segment, as determined by the address and D0 logic level, is then latched when the enable line returns to logic 1.

The data lines are connected directly to the various devices in the system. Data buffers IC9 and IC10 are bus transceivers. They are wired to normally provide output from the data lines to the data terminals. Connecting \bar{RE} to logic 0 reverses the input output pins so you can input data from the connectors.

BINARY DATA SECTION

The eight section data switch has one side of all switches connected to ground. The other side of each section has a 4700 ohm pull-up resistor to the switched 5 V power supply. The connectors above the

switch provide convenient connection for two wires to each switch section. With a switch in the lower (closed) position, the associated terminal will provide a logic 0 level (ground). In the up (open) position the level will be logic 1. The switch sections are numbered 0 through 7 from right to left. The eight connectors numbered 0 through 7 are inputs to the non-inverting buffer IC1. An 8200 ohm pull-down resistor is connected through each input terminal to ground to hold the input at logic 0 when no connection is made to the terminals. Each buffer output is connected through an LED and a 180 ohm current-limiting resistor to ground. When the inputs to the buffer are logic 0, the outputs are also 0 and the LED is off. When the input rises to logic 1, the output also rises to logic 1 and lights the LED.

POWER SUPPLIES

The voltage from one of the center-tapped secondary windings (green leads) of power transformer T1 is rectified by diodes D1 and D2, filtered by capacitor C1, and regulated by IC31 to produce the +5-volt DC supply. With switch SW1 in the On position, +5 volt is supplied throughout the system. When SW1 is in the Standby position, +5 volt is not supplied to the display LED's, data switches, or the +5 V connector block.

The other center-tapped secondary winding (red) is rectified by diodes D3 and D5, filtered by C7, and regulated by IC30 to provide a -12-volt supply. This same winding is rectified by diodes D4 and D6, filtered by C6, and regulated by IC29 to provide a +12-volt supply. These two supplies are provided for bread-boarding and are not connected in the system. They are available at the appropriate connector blocks only when switch SW1 is in the On position.

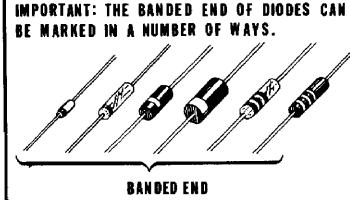

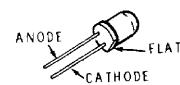

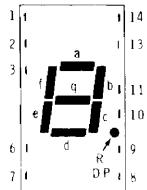

SQUARE WAVE OUTPUTS

The AC voltage at the anode of diode D6 is coupled by R5 and R6 to a section of voltage comparator IC18. Diode D10 keeps the AC voltage from driving the input negative with respect to ground. This section of the comparator is a zero-crossing detector to provide a symmetrical TTL compatible square wave that is in sync with the AC line.

A second section of IC18 is used as an oscillator to produce a TTL compatible square wave at approximately 1 Hz. The symmetry and frequency of the square wave are determined by C13, R13, and R14.

CUSTOMER SERVICE

REPLACEMENT PARTS

Please provide complete information when you request replacements from either the factory or Heath Electronic Centers. Be certain to include the HEATH part number exactly as it appears in the parts list.

ORDERING FROM THE FACTORY

Print all of the information requested on the parts order form furnished with this product and mail it to Heath. For telephone orders (parts only) dial 616 982-3571. If you are unable to locate an order form, write us a letter or card including:

- Heath part number.
- Model number.
- Date of purchase.
- Location purchased or invoice number.
- Nature of the defect.
- Your payment or authorization for COD shipment of parts not covered by warranty.

Mail letters to: Heath Company
Benton Harbor
MI 49022
Attn: Parts Replacement

Retain original parts until you receive replacements. Parts that should be returned to the factory will be listed on your packing slip.

OBTAINING REPLACEMENTS FROM HEATH ELECTRONIC CENTERS

For your convenience, "over the counter" replacement parts are available from the Heath Electronic Centers listed in your catalog. Be sure to bring in the original part and purchase invoice when you request a warranty replacement from a Heath Electronic Center.

TECHNICAL CONSULTATION

Need help with your kit? — Self-Service? — Construction? — Operation? — Call or write for assistance. You'll find our Technical Consultants eager to help with just about any technical problem except "customizing" for unique applications.

The effectiveness of our consultation service depends on the information you furnish. Be sure to tell us:

- The Model number and Series number from the blue and white label.
- The date of purchase.
- An exact description of the difficulty.
- Everything you have done in attempting to correct the problem.

Also include switch positions, connections to other units, operating procedures, voltage readings, and any other information you think might be helpful.

Please do not send parts for testing, unless this is specifically requested by our Consultants.

Hints: Telephone traffic is lightest at midweek — please be sure your Manual and notes are on hand when you call.

Heathkit Electronic Center facilities are also available for telephone or "walk-in" personal assistance.

REPAIR SERVICE

Service facilities are available, if they are needed, to repair your completed kit. (Kits that have been modified, soldered with paste flux or acid core solder, cannot be accepted for repair.)

If it is convenient, personally deliver your kit to a Heathkit Electronic Center. For warranty parts replacement, supply a copy of the invoice or sales slip.

If you prefer to ship your kit to the factory, attach a letter containing the following information directly to the unit:

- Your name and address.
- Date of purchase and invoice number.
- Copies of all correspondence relevant to the service of the kit.
- A brief description of the difficulty.
- Authorization to return your kit COD for the service and shipping charges. (This will reduce the possibility of delay.)

Check the equipment to see that all screws and parts are secured. (Do not include any wooden cabinets or color television picture tubes, as these are easily damaged in shipment. Do not include the kit Manual.) Place the equipment in a strong carton with at least THREE INCHES of resilient packing material (shredded paper, excelsior, etc.) on all sides. Use additional packing material where there are protrusions (control sticks, large knobs, etc.). If the unit weighs over 15 lbs., place this carton in another one with 3/4" of packing material between the two.

Seal the carton with reinforced gummed tape, tie it with a strong cord, and mark it "Fragile" on at least two sides. Remember, the carrier will not accept liability for shipping damage if the unit is insufficiently packed. Ship by prepaid express, United Parcel Service, or insured Parcel Post to:

PAGE 1 OF 1

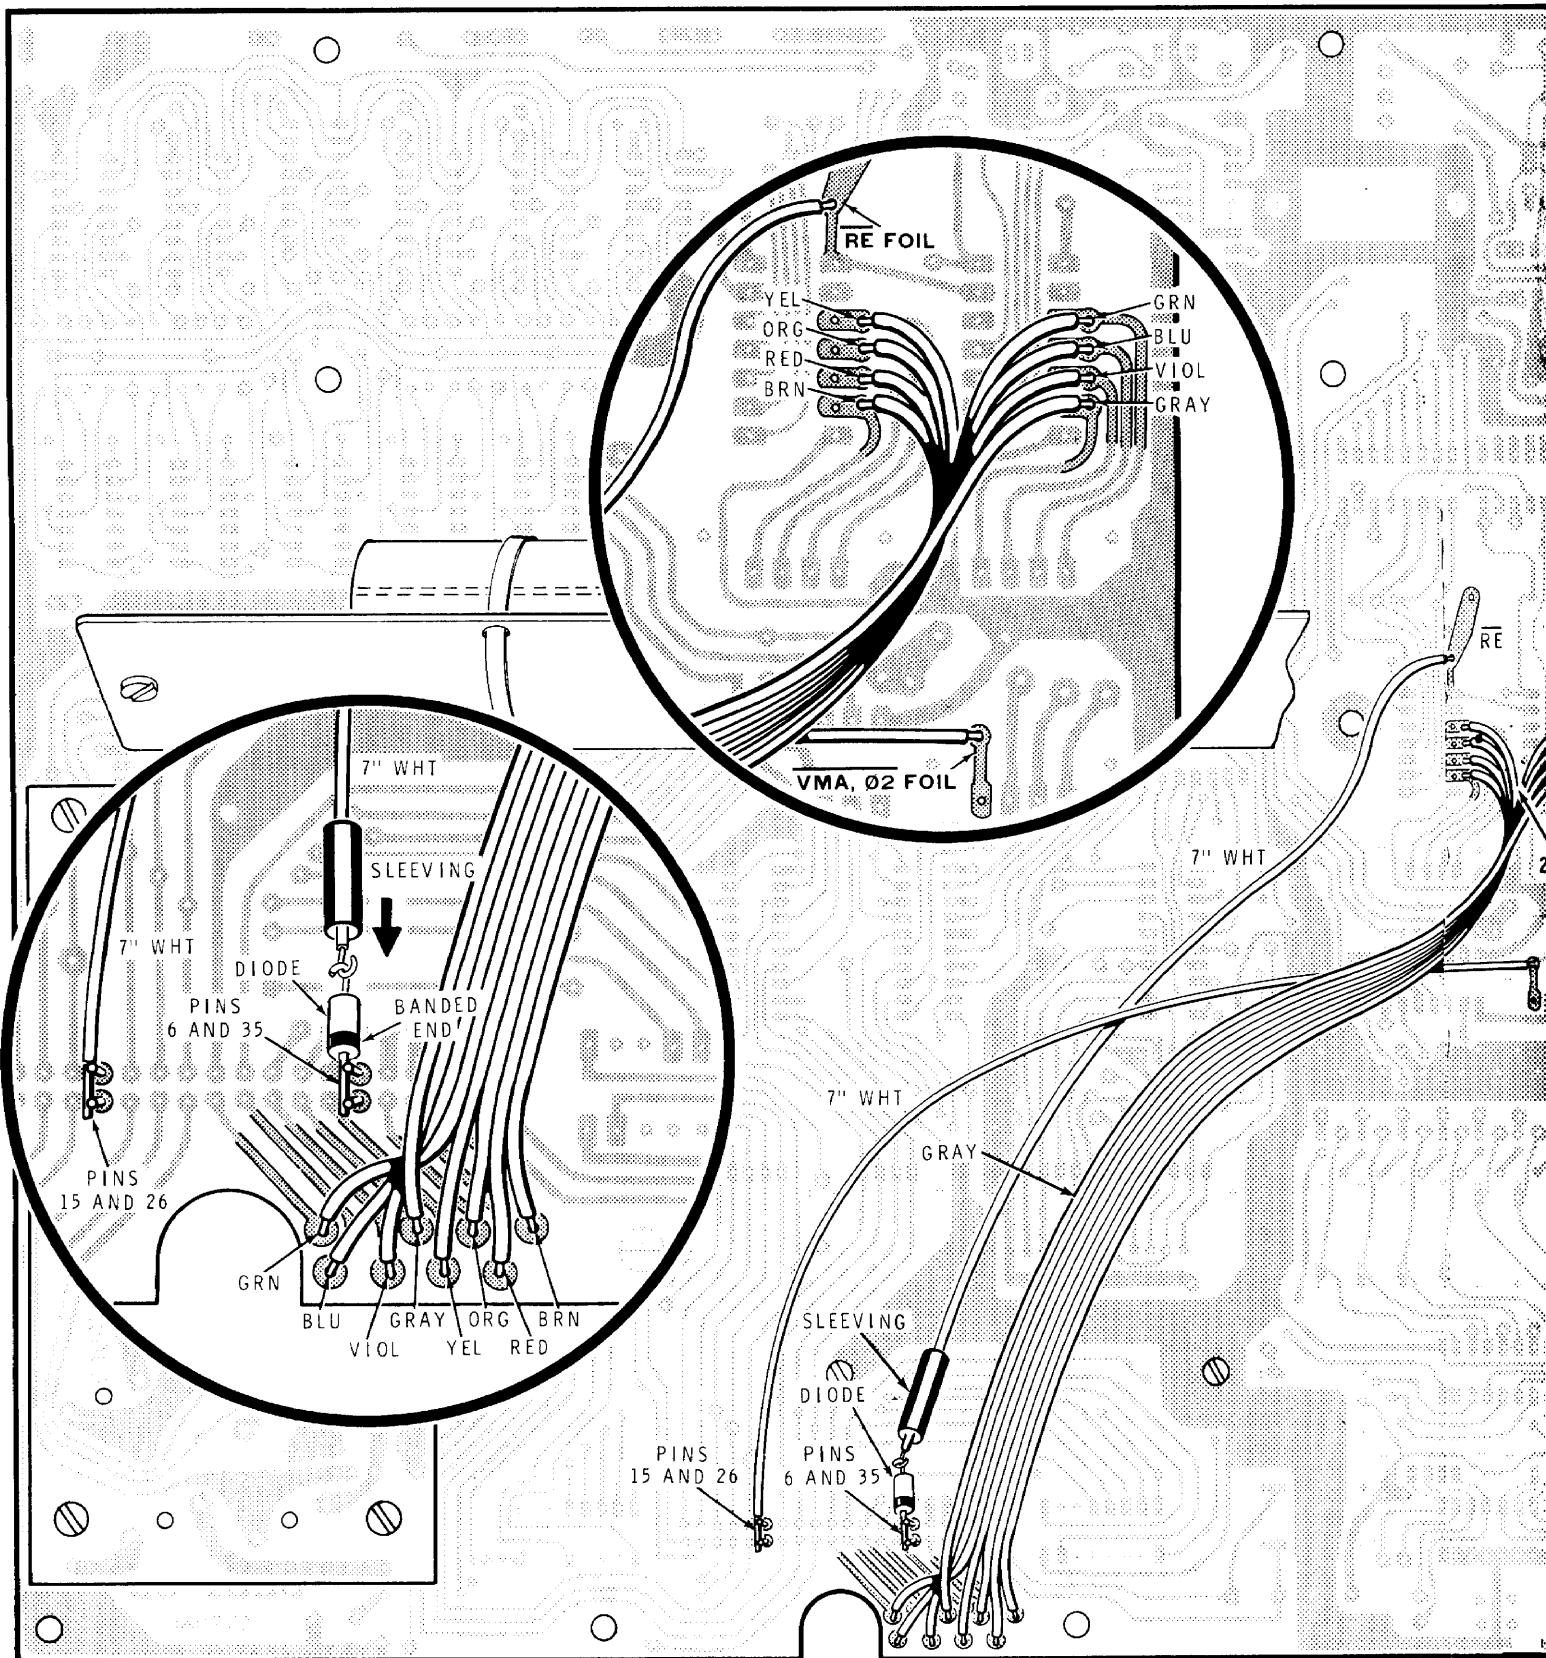

KEEP THIS PARTS LIST WITH YOUR MANUAL AND USE THE PRICES SHOWN BELOW WHEN ORDERING PARTS. THESE PRICES ARE SUBJECT TO CHANGE WITHOUT NOTICE.

THE PRICES SHOWN ON THE "HEATH PARTS PRICE LIST" APPLY ONLY ON PURCHASES FROM THE HEATH COMPANY WHERE SHIPMENT IS TO A U.S.A. DESTINATION. ADD 10% (MINIMUM 25 CENTS) TO THE PRICE WHEN ORDERING (MICHIGAN RESIDENTS ADD 4% SALES TAX) TO COVER INSURANCE, POSTAGE, AND HANDLING. OUTSIDE THE U.S.A., PARTS AND SERVICE ARE AVAILABLE FROM YOUR LOCAL HEATHKIT SOURCE AND WILL REFLECT ADDITIONAL TRANSPORTATION, TAXES, DUTIES, AND RATES OF EXCHANGE.

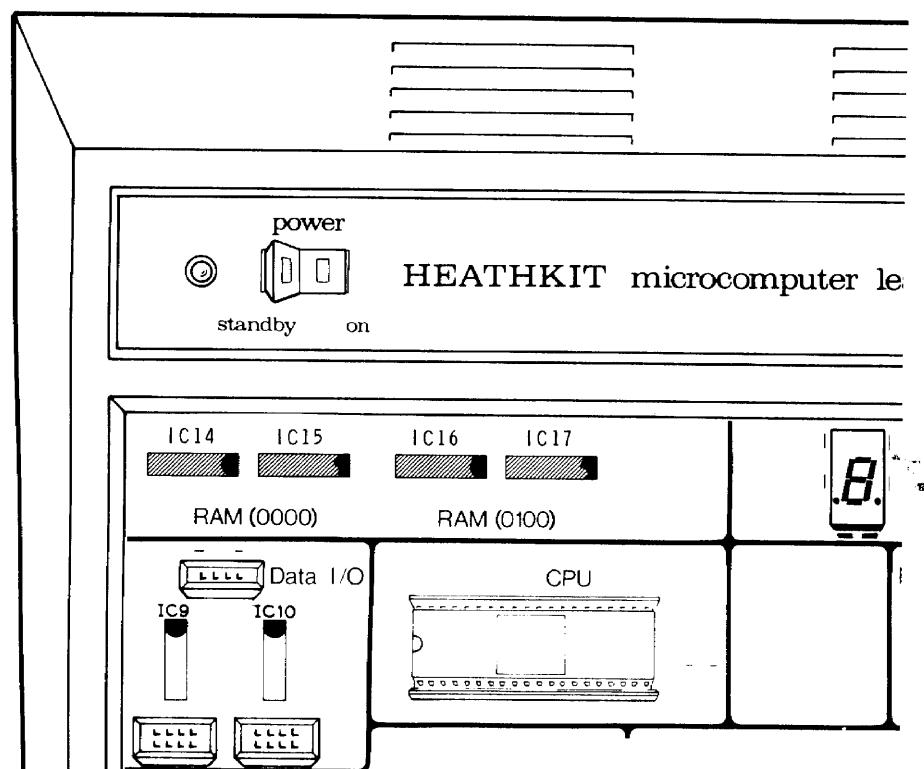

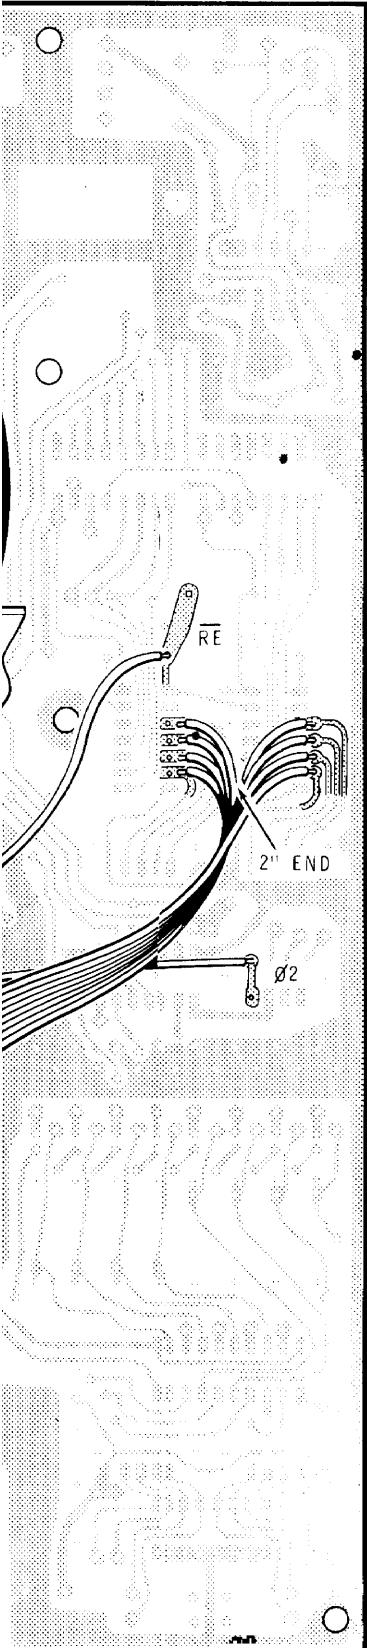

ADDITIONAL 3 FT ROLLS OF SOLDER, #331-6, CAN BE ORDERED FOR 25 CENTS EACH.

CIRCUIT BOARD X-RAY VIEW

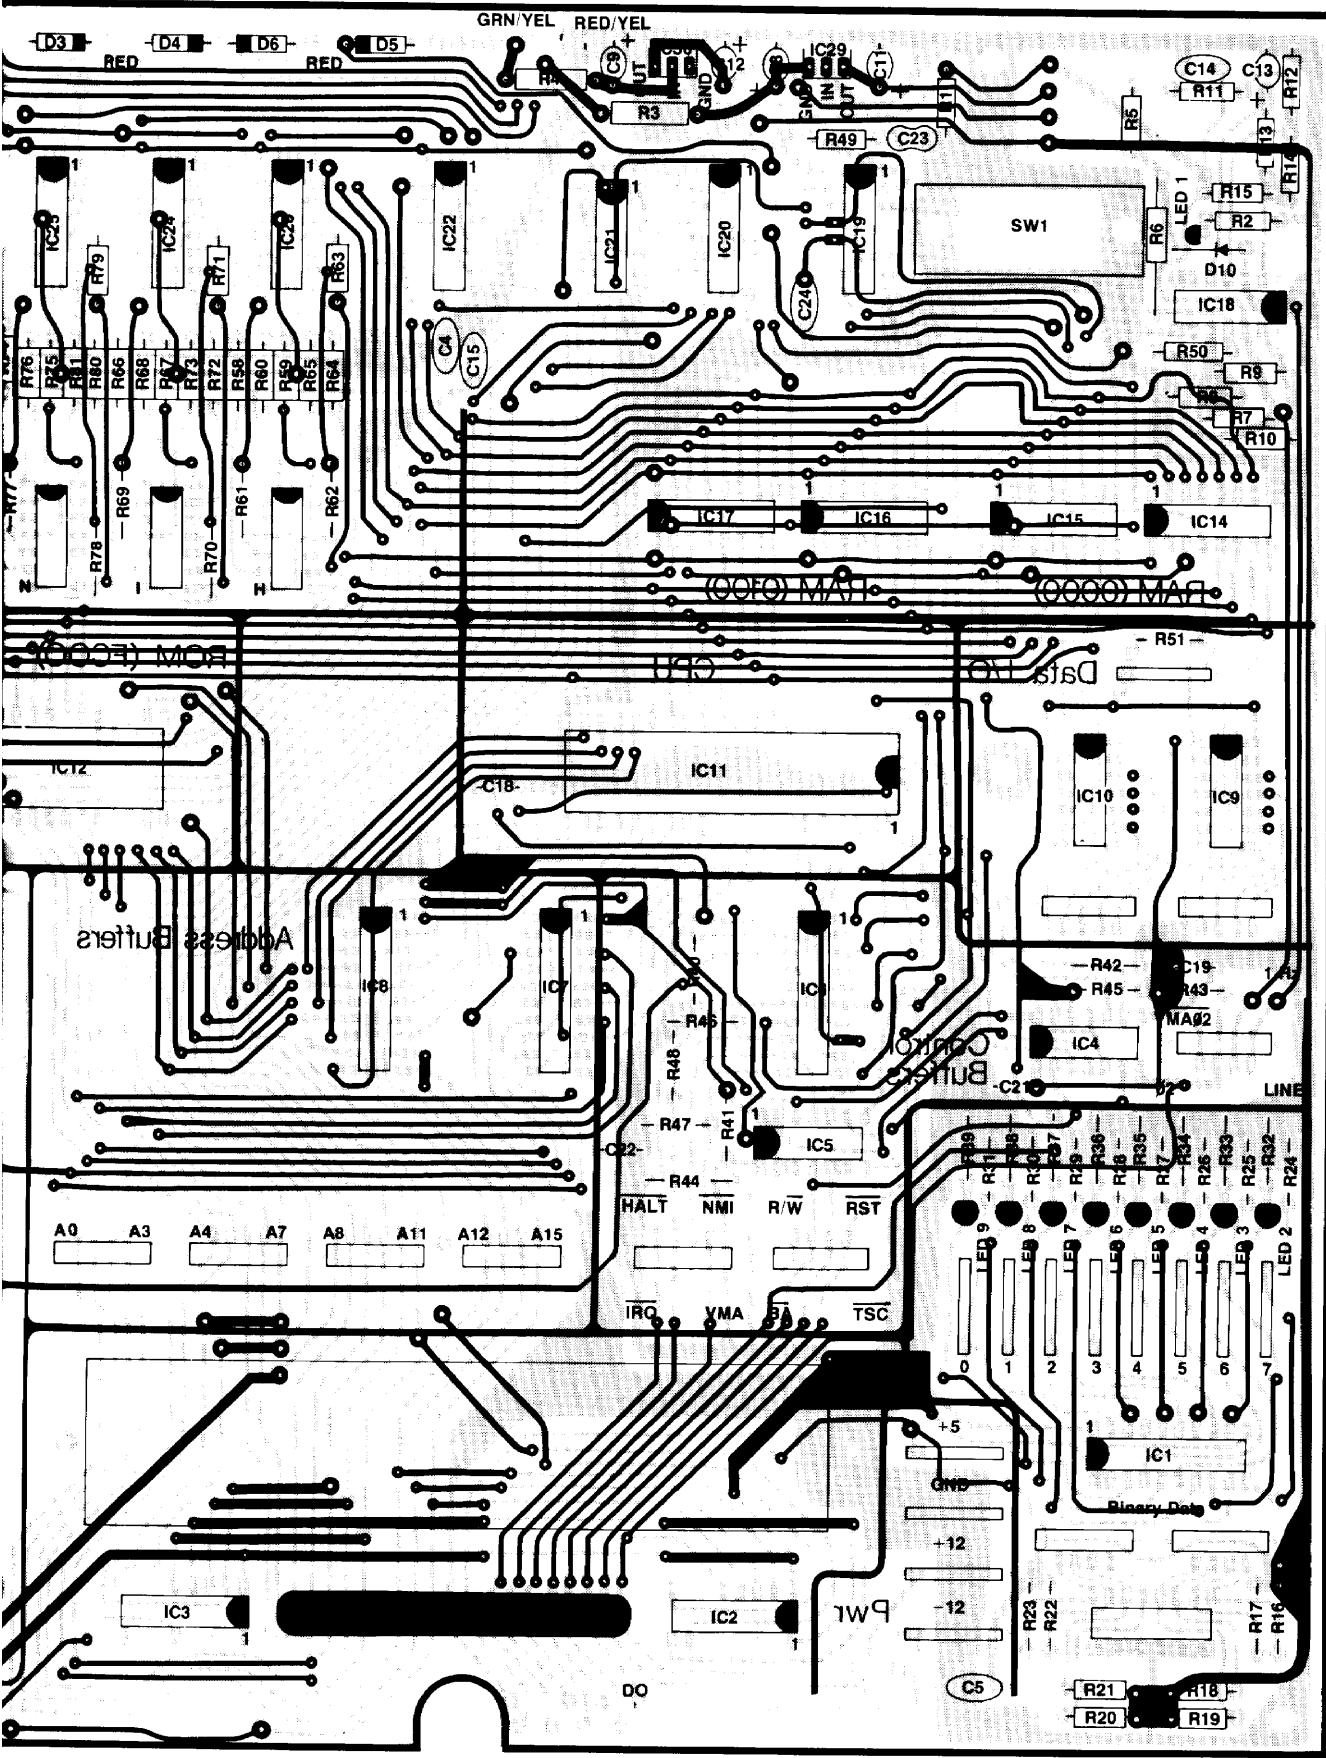

NOTE: To find the PART NUMBER of a component for the purpose of ordering a replacement part:

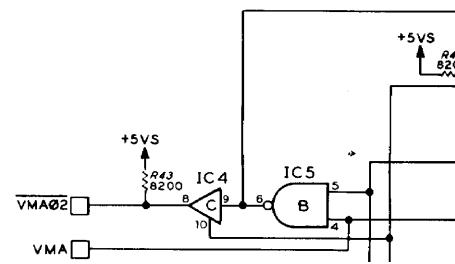

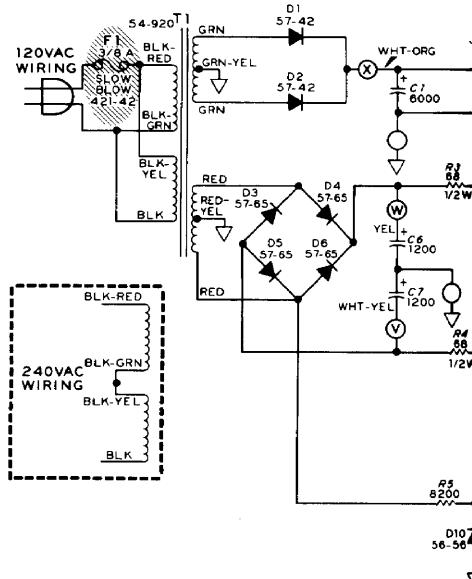

- A. Find the circuit component number (R5, C3, etc.) on the "X-Ray View."
- B. Locate this same number in the "Circuit Component Number" column of the "Parts List."
- C. Adjacent to the circuit component number, you will find the PART NUMBER and DESCRIPTION which must be supplied when you order a replacement part.
